with the PHS, USDHEW

DHEW Publication No. (NIH) 78-66

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
amp	ampere
ATP	adenosine triphosphate
A	angstrom
BSP	sulfobromophthalein
C	degrees centigrade
cal	calories
cc	cubic centimeter
cm	centimeter(s)
dl	deciliter
DNA	deoxyribonucleic acid
ED_{50}	median effective dose(s)
EDTA	ethylenediamine tetraacetic acid
e.g.	for example
EEG	electroencephalogram
ESR	erythrocyte sedimentation rate
g	gram(s)
µg	microgram(s)
Hz	Hertz
hr	hour(s)
Ig	immunoglobulin(s)
i.m.	intramuscular
i.p.	intraperitoneal
IU	international unit(s)
i.v.	intravenous
kcal	kilocalorie(s)
kg	kilogram(s)
K_m	Michaelis constant
LD_{50}	median lethal dose(s)
LDH	lactic acid dehydrogenase
m	meter(s)
M	molar; mole(s)
mM	millimolar; millimole(s)
µM	micromolar; micromole(s)
ma	milliampere(s)
mCi, µCi	milli-, microcurie(s)
mEq	milliequivalent(s)
mg	milligram(s)

ml, µl	milli-, microliter(s)
mm	millimeter(s)
mOsm	milliosmolar; milliosmeter(s)
msec	millisecond(s)
mV	millivolt(s)
min	minute(s)
MTD	maximum tolerated dose
NAD	nicotinamide adenine dinucleotide
NADH	reduced nicotinamide adenine dinucleotide
NADP	nicotinamide adenine dinucleotidephosphate
NADPH	reduced nicotinamide adenine dinucleotidephosphate
ng	nanogram (10^{-9})
nm	nanometer(s)
Pa	ambient pressure
PAS	periodic acid - Schiff
pg	picogram (10^{-12})
pgEq	picogram equivalent(s)
p.o.	orally
ppb	parts per billion
ppm	parts per million
r	Roentgen
RBC	red blood cells (erythrocytes), red blood count
resp.	respectively
RNA	ribonucleic acid
s.c.	subcutaneous
sec	second(s)
SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations

Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0001 MICROSTRUCTURE OF THE PARENCHYMA IN THE AREA OF THE HEPATIC LOBULES. (Ger.) Meitner, E. R.; Proksova, E. G.; Baranova, M. (Lehrstuhl fur Histologie und Embryologie, Muzealna 6, 036 01 Martin, Czechoslovakia). *Anat. Anz.* 139 (1/2):36-57; 1976.

The problem of human and animal hepatic lobular microarchitecture is reviewed and the historic question of two-layered cords or one-layered plates is re-examined. Particular attention was devoted to the three-dimensional model, similar to the Elias reconstructions. The liver parenchyma was projected from six visual fields and the nuclei were joined by lines. In adjacent pictures, it was clearly visible that only 1-cell rows existed between the sinusoids in the majority of cases, excepting only anastomoses and certain clustered areas. These line drawings were entirely compatible with the acid phosphatase staining patterns. In spatial representation, the Remakian cords then appear as lamina or plates built up from cells which are not so much next to one another as over or under each other. The correct imagery would be of a single wall of bricks (hepatocytes) lying between two sinusoids.

0002 ELECTRON-MICROSCOPIC STUDIES ON DEVELOPING INTRAMURAL GANGLIA OF THE SMALL INTESTINE IN HUMAN AND RABBIT FETUSES. (Eng.) Daikoku, S.; Ikeuchi, C.; Miki, S. (Sch. Medicine, Tokushima Univ., Japan). *Acta Anat. (Basel)* 91(3):429-454; 1975.

The electron microscope was used to study Auerbach's plexus in developing human and rabbit small intestine, particularly the relation between morphogenesis and intestinal motility. No muscle layer was seen in the first stage of development (human, 6-7 weeks; rabbit, 12-14 days). Neuroblasts were round or oval, varying in size and in cytoplasmic appearance. Neural and glial processes (0.1-1.0 µm), with numerous tubular structures, were found abutting the neural cells. At the second stage, (human, 8-9 weeks; rabbit, 15-18 days), the Auerbach's plexus with ganglia was spread over the outside of the muscle layer and bidirectional peristalsis occurred. Three types of synaptic profiles were seen: (a) little membrane specificity on the synaptic portion; (b) small flattened vesicles; and (c) small round vesicles. The third stage (human, 10-12 weeks; rabbit, 20 days), showed development of the longitudinal muscle layer and nerve terminals containing mainly cored vesicles of two types: large (1,100-1,300 A) homogeneous dense granules with a limiting membrane, and numerous medium-sized (500-900 A) vesicles with a dense core and smaller sized vesicles (400-600 A) of slightly electron-opaque material. By the fourth stage (human, 27-30 weeks; rabbit, 26-31+ days) antiperistalsis no longer occurred. A new type of nerve terminal could be distinguished at this phase, one with dense, axoplasmic ground matrix, densely packed with cored vesicles (600-1300 A). The physiological significance of the different types of nerve terminals remains to be determined.

0003 ABOUT ARGENTAFFINITY AND ARGYROPHILIA OF CERTAIN ENDOCRINE GLANDS OF THE DIGESTIVE MUCOSAS. (Fre.) LeFranc, G.; Pradal, G.; L'Hermite, A.; Tusques, J. (Laboratoire d'Histologie et Embryologie, Faculte de Medecine, 44 Nantes, France). *Ann. Histochim.* 20(1):67-76; 1975.

The effect of amine loading on the argentaffin and argyrophilic properties of mucosal glands in the gastrointestinal tracts of rabbits and mice was examined. The fluorescence of endocrine gland cells (Falck's technique) in mice and in fetal, neonatal, and adult rabbits, which had or had not received L-Dopa, was compared relative to reductive, argentaffin, and argyrophilic response. These studies on cell differentiation showed that, although L-Dopa can potentiate or diminish the argentaffin sensitivity of a cell, its presence is neither necessary nor sufficient in the reduction of silver salts. The effect is nonspecific, since argyrophilia can also be potentiated or decreased.

0004 ULTRASTRUCTURAL ASPECT OF HUMAN AND MURINE DUODENAL EXPLANTS MAINTAINED IN CULTURE TYPICAL FOR THE ORGAN FOR 24 HR [Abstract]. (Fre.) Ferland, S.; Berteloot, A.; Maestracci, D.; Hugon, J. S. (Centre Hospitalier Universitaire, Universite de Sherbrooke, Sherbrooke, P.Q. J1H 5N4, Canada). *J. Microsc. Biol. Cell.* 23(2):46-47; 1975.

0005 HISTOLOGICAL EFFECTS OF DUCTAL LIGATION OF SALIVARY GLANDS OF THE CAT. (Eng.) Harrison, J. D.; Garrett, J. R. (King's Coll. Hosp. Dental Sch., London SE5 8RX, England). *J. Pathol.* 118(4):245-254; 1976.

0006 VEGETATIVE INNERVATION OF THE ESOPHAGUS: IV. ENDINGS IN THE TELA SUBMUCOSA AND TUNICA MUSCULARIS. (Eng.) Pedrosa, J. A.; Hernandez, C. J.; Rodrigo, J.; Vidal, M. A. (Instituto Cajal, CSIC, C/Velazquez 144, Madrid 6, Spain). *Acta Anat. (Basel)* 95(3):452-467; 1976.

0007 ARCHITECTURE OF THE MUSCULATURE AT THE GASTROESOPHAGEAL JUNCTION AND IN THE FUNDUS. (Eng.) Liebermann-Meffert, D. (Kantonsspital, Univ. Basel, Basel, Switzerland). *Chir. Gastroenterol.* 9(4):425-429; 1975.

0008 INTESTINAL DISTRIBUTION OF CRYSTAL-LIKE AND CRYSTAL CONTAINING CELLS IN THE RAT

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

AND MOUSE. (Spa.) Gonzalez-Licea, A. (Departamento de Investigacion en Medicina Experimental, Centro Medico Nacional, Instituto Mexicano del Seguro Social, Apdo. Postal 73-032 Mexico 12, D.F.). *Arch. Invest. Med.* 7(1):49-56; 1976.

0009 CHOLINERGIC INNERVATION OF THE SIMIAN OXYNTIC GASTRIC MUCOSA. (Eng.) Lechago, J.; Barajas, L. (UCLA Sch. Medicine, Torrance, CA 90509). *Am. J. Anat.* 147(1):147-152; 1976.

0010 ALDEHYDE-FUCHSIN STAINING OF ANTRAL ENDOCRINE CELLS. (Eng.) Ghiringhello, B.; Bussolati, G. (II Istituto di Anatomia ed Istologia Patologica, Univ. Torino, Via Santena 7, 1-10126 Torina, Italy). *Histochemistry* 48(2):145-152; 1976.

0011 ULTRASTRUCTURAL STUDY OF THE ERYTHROPOIETIC EVENTS IN HUMAN EMBRYONIC LIVERS. (Eng.) Djaldetti, M.; Ovadia, J.; Bessler, H.; Fishman, P.; Halbrecht, I. (Hasharon Hosp., Petah Tiqva, Israel). *Biol. Neonate* 26(5/6):367-374; 1975.

0012 AGE-RELATED CHANGES IN HEPATIC FINE STRUCTURE: A QUANTITATIVE ANALYSIS. (Eng.) Schmucker, D. L. (Veterans Admin. Hosp., San Francisco, CA). *J. Gerontol.* 31(2):135-143; 1976.

0013 A MORPHOMETRIC STUDY OF THE DENSITY OF MITOCHONDRIAL CRISTAE IN HEART AND LIVER OF AGING MICE. (Eng.) Tate, E. L.; Herbener, G. H. (Univ. Louisville Sch. Medicine, Health Sciences Center, Louisville, KY 40201). *J. Gerontol.* 31(2):129-134; 1976.

0014 ELECTRICAL SIZING OF LIVER CELL NUCLEI BY THE PARTICLE BEAM METHOD. MEAN VOLUME, VOLUME DISTRIBUTION AND ELECTRICAL RESISTANCE. (Eng.) Valet, G.; Silz, S.; Metzger, H.; Ruhenstroth-Bauer, G. (Max-Planck-Institut fur Biochemie, 8033 Martinsried b. Munchen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 22(5):274-281; 1975.

0015 THE ROLE OF CATIONS AND SUPERFICIAL MEMBRANE PROTEINS IN THE RAT LIVER PARENCHYMA CELL ADHESION. II. EFFECTS OF CA^{2+} IONS ON THE STRUCTURE OF CELLULAR CONTACTS. (Rus.) Komissarchik, I. I.; Snigirevskaia, E. S.; Vinnichenko, L. N.; Ivanovskaia, E. G. (Inst. Cytology, Acad. Sci. Leningrad, USSR). *Tsitologiia* 18(5):575-579; 1976.

ABSORPTION - EXCRETION - TRANSPORT

0016 ABSORPTION OF AMINO ACIDS AND PEPTIDES FROM A COMPLEX MIXTURE IN THE ISOLATED SMALL INTESTINE OF THE RAT. (Eng.) Gardner, M. L. G. (Univ. Edinburgh Medical Sch., Teviot Place, Edinburgh, EH8 9AG, Scotland). *J. Physiol. (Lond.)* 253(1):233-256; 1975.

To gain information on the relative physiological importance of peptide and amino acid absorption, the absorption of 16 amino acids, both free and peptide-bound, was measured in the isolated perfused rat small intestine from a pancreatic partial digest of casein. The perfusate included the following amino acids at concentrations from 20 to 500 µM: aspartic acid, threonine, serine, glutamic acid, proline, glycine, alanine, valine, methionine, isoleucine, leucine, tyrosine, phenylalanine, histidine, lysine, and arginine. The rate of absorption of each acid was closely proportional to its concentration in the perfusate, implying a constant V_{max}/K_m ratio for all amino acids in the mixture. There was a high correlation between the compositions of luminal perfusate and secretion into the tissue fluid (apart from the content of glutamic and aspartic acids and alanine). The concentrations of each free amino acid were, on the average, nine times as great in secretion as in the lumen; the total peptide-N concentration in secretion was approximately four times that in the lumen. The rate of absorption of each free amino acid ($p<0.001$) was highly negatively dependent on the rate of absorption of that amino acid in peptide-bound form ($p<0.001$), in addition to being positively dependent on the perfusate concentration of free amino acid. Peptide-bound proline appeared to be well absorbed; free proline liberated by hydrolysis appeared to pass back into the lumen as well as into the tissue fluid. About one-third of the amino acids appearing in the secretion on the serosal surface were peptide-bound. The results suggest that the rate of absorption of peptides determines the rate of their hydrolysis, which probabl occurs mainly after entry into the mucosal cells.

0017 KINETICS OF THE SUBCELLULAR DISTRIBUTION OF IRON AND COBALT IN THE INTESTINAL MUCOSA OF THE RAT. (Eng.) Thomson, A. B. R.; Valberg, L. S. (Dept. Medicine, Clinical Sciences Bldg., Univ. Alberta, Edmonton, Alberta, Canada T6G 2G3). *Am. J. Dig. Dis.* 21(4):305-312; 1976.

The subcellular distribution of labeled Fe and Co in Fe-deficient rats (FeD), in which transport was active, was compared by a differential centrifugation technique with that in Fe-loaded rats (FeL), in which transport was by diffusion. Solutions containing either Fe or Co in concentrations varying from 0.1 to 10.0 mM were perfused for 30 min through duodenal loops of FeD and FeL rats. In FeL rats, a linear relation was observed between the concentration of metal in the perfusate and the amount of Fe and Co in each subcellular fraction. More Fe and Co was present in each fraction from FeD animals than from FeL animals. The addition of 2 mM Co to the Fe perfusate reduced the uptake and transfer of Fe, with a reduction ($p<0.05$) in the amount of Fe in fractions I and II at concentrations of 2, 5, and 10 mM. The addition of Fe, varying from 0.1 to 10 mM, to the 2-mM perfusate of Co caused a reduction in Co uptake and transfer and a reduction ($p<0.05$) in the amount of Co in fractions II-V. The average amount of Fe in the mucosa of the duodenum of FeL animals was 108 ± 32 nmol, as compared to 219 ± 27 nmol in normal animals. The increase was due to the presence of more Fe in fractions I and II ($p<0.05$). In FeD animals, there was a further increase in the amount of Fe in the mucosa (595 ± 63 nmol). The average amount of Co in the mucosa was 228 ± 49 nmol, most of which was in fraction V. Although there is an overlap in the fractions prepared by differential centrifugation, the specific subcellular composition of each fraction was not identified in this experiment. This centrifugation technique is useful, however, for indicating which crude fractions should be subsequently examined by a more sensitive technique. The results suggest that a constituent(s) in the particulate fractions I and II is involved in the enhanced absorption of Fe in FeD animals. The subcellular fraction responsible for the increased Co absorption in FeD rats was not identified.

0018 TRANSPORT OF SODIUM AND POTASSIUM IN INTESTINAL EPITHELIAL CELLS. (Eng.) Rose, R. C. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Coll. Medicine, Hershey, PA 17033). *Life Sci.* 18(11):1229-1236; 1976.

Transport properties of rabbit small intestinal mucosa were investigated *in vitro* to characterize the process by which epithelial cells maintain normal Na and K gradients across the cell membrane. Individual samples of freshly excised ileal mucosa were incubated in HCO_3-buffer or in K-free buffer, and the intracellular Na concentration was determined. The intracellular Na concentration was reduced more rapidly ($p<0.01$) in the presence of K than in its absence. Tissue incubated in the presence of Na accumulated K at a significantly greater rate ($p<0.05$) than tissue incubated in Na-free buffer. Following preincubation at 0 C in K-free buffer to reduce the K concentration, a greater transmural electrical potential difference (+0.92 ± 0.4 mV) and short circuit current (+45 ± 18 $\mu amp/cm^2$, $p<0.01$) developed as the temperature was increased to 37 C, if K_2 (10 mEq/l) was present in the bathing solution. The potential difference and short circuit current, which generally reflect the rate of active Na transport in the ileum under control conditions, increased immediately upon raising the K concentration in the serosal solution from 0 to 10 mM. The results present the first direct indication in mammalian intestine of an interdependence of the Na and K active transport processes, which regulate the intracellular content of these cations.

0019 GASTROINTESTINAL ABSORPTION. I. MECHANISMS. (Eng.) Blanchard, J. (Coll. Pharmacy, Univ. Arizona, Tucson, AZ 85721). *Am. J. Pharm.* 147(5):135-146; 1975.

0046 INHIBITORY EFFECTS OF ADENINE NUCLEOTIDE ANALOGS ON THE ISOLATED GUINEA-PIG TAENIA COLI.

(Eng.) Satchell, D. G.; Maguire, M. H. (Dept. Zoology, Univ. Melbourne, Parkville, Victoria, Ausralia). *J. Pharmacol. Exp. Ther.* 195(3):540-548; 975.

he inhibitory actions of ADP, AMP, adenosine, and 6 adenine nucleotide and nucleoside analogs on solated guinea pig taenia coli preparation were comared with those of ATP. Responses were quantitated s the magnitude of maximal relaxation, time taken o reach maximal relaxation, and activity relative o that of ATP. Inhibitory responses induced by the '-di- and triphosphates of 2-chloroadenosine and -methyl-thioadenosine resembled those elicited by DP and ATP, but the 2-substituted analogs were arkedly more potent. AMP and adenosine were less ctive than ATP; their activities were enhanced by -chloro substitution but not by 2-methylthio subtitution. 2-Methylthio-AMP and 2-methylthioadenosine ere the only analogs that did not elicit maximal elaxation of the taenia coli. 6'-Deoxyhomoadenosine '-phosphonic acid was inactive. Adenine nucleotide nalogs in which the polyphosphate moiety was modiied had steeper log dose-response curves and inuced greater maximal responses than ATP. Analogs n which the polyphosphate α,β-anhydride oxygen as replaced by methylene took up to five times onger than ATP to cause maximal relaxation. Other nalogs with modified or unmodified polyphosphate ide chains caused rapid relaxation of the taenia oli. There was no apparent correlation between reative activity and time to reach maximal response. he findings indicate that di- or triphosphate groupngs are of prime importance in binding adenine nuleotides to the putative smooth muscle receptor that ediates their inhibitory responses, and that hyrolysis of the terminal phosphates of adenosine '-polyphosphates is not a requirement for inhibitory ctivity.

047 EFFECT OF METOCLOPRAMIDE ON MYOELECTRICAL AND MECHANICAL ACTIVITY OF THE ISOLATED ANINE STOMACH PERFUSED EXTRACORPOREALLY.

(Eng.) owalewski, K.; Kolodej, A. (Surgical-Medical Res. nst., Univ. Alberta, Edmonton, Alberta T6G 2N8, anada). *Pharmacology* 13(6):549-562; 1975.

ne effect of metoclopramide on myoelectrical and echanical activity was studied in the totally isoated canine stomach, perfused extracorporeally. ne stomachs were perfused with homologous blood f living supporting dogs. Drugs were administered irectly into the arterial system of the isolated tomachs, either as flash injections or as constant nfusions. Flash injections of metoclopramide (2.5 g) led to the response activity (spiking) and associated mechanical response. Electrical control ctivity was also affected by metoclopramide; the hanges consisted of premature control activity and ncoupling. Similar reactions were observed after flash injections of 5 µg methacholine, 5 µg pentagastrin, or electrical stimulation (15V 8 Hz 5 msec) of the Latarjet nerve. These reactions were dose-dependent. When given as a constant infusion, tetrodotoxin (100 µg/hr for 30 min), atropine (0.2 mg/hr for 10 min), hexamethonium (150 mg/hr for 15 min), and glucagon (5 mg/hr for 40 min) inhibited the action of metoclopramide on myoelectrical and mechanical activities of the isolated stomach. Inhibitions of the responses to metoclopramide by atropine and tetrodotoxin implicate acetylcholine in the mediation of these responses. The ability of hexamethonium to diminish the response to metoclopramide suggests that a locus of action may be at both pre- and post-ganglionic sites of the intramural plexus. Exact receptors of this action were not demonstrated.

0048 CONTRACTION OF ISOLATED BRUSH BORDERS FROM THE INTESTINAL EPITHELIUM.

(Eng.) Rodewald, R.; Newman, S. B.; Karnovsky, M. J. (Dept. Biology, Univ. Virginia, Charlottesville, VA 22901). *J. Cell Biol.* 70(3):541-554; 1976.

The contraction of brush borders isolated from the epithelial cells of the small intestine of neonatal rats was studied by light and electron microscopy. These brush borders were able to contract in the presence of ATP and Mg^{2+}; Ca^{2+} was not required. Contraction was characterized by a pinching-in of the plasma membrane in the region of the zonula adherens and a subsequent rounding of the brush borders. No movement or consistent shortening of the microvilli was observed. The most noteworthy feature of the internal contents of the brush borders was the large number of the microfilaments. Three groups of filaments were differentiated: core filaments of the microvilli, terminal web filaments, and tonofilaments. The contraction appeared to involve the 5- to 7-nm diameter microfilaments in the terminal web, which were associated with the zonula adherens. After exposure to meromyosin (HMM, 2 mg/ml) for 30 min, both the core filaments of the microvilli and the terminal web filaments bound HMM. If it is assumed that the core filaments of the microvilli and the terminal web filaments associated with the zonula adherens exhibit the same polarity with regard to their respective attachment sites on the plasma membrane, then the interaction of these filaments with myosin molecules in the terminal web would generate tension between the zonula adherens and the tips of the microvilli. With isolated brush borders, the tension would cause a contraction confined primarily to the terminal web, with a contraction like that seen in this study. It is postulated that in the intact tissue, the zona adherens, by virtue of its location within the junctional complex between cells, is most likely restrained from appreciable movement; the tension exerted within the terminal web might be sufficient to overcome the rigidity of the microvillar membranes and cause shortening of the microvilli.

SECRETION AND METABOLISM

0071 THE INHIBITORY INFLUENCE OF THE PYLORIC ANTRUM ON GASTRIC SECRETION IN DOGS. (Eng.) Hunt, D. R.; Forrest, A. P. M. (Welsh National Sch. Medicine, Cardiff, Wales). *Aust. J. Exp. Biol. Med. Sci.* 54(1):79-89; 1976.

The effects of denervation of the pyloric antrum and of subsequent vagotomy on the secretory responses of an innervated or a denervated gastric pouch to histamine and pentagastrin were determined in mongrel dogs. Each animal received seven doses of 5, 10, 20, 40, 80, 160, and 320 μg histamine base/kg/hr as histamine acid phosphatase or 0.5, 1, 2, 4, 8, 16, and 32 μg/kg/hr of pentagastrin by continuous i.v. infusion at a rate of 21.4 ml/hr. In dogs with innervated gastric pouches, maximal acid output was produced by 160 μg/kg/hr histamine, although in any single test, the peak sometimes occurred at the dose above or below this level. The same pattern occurred after denervation of the antrum, but the output of acid was significantly greater at all doses above 20 μg/kg/hr. For the pentagastrin stimulus, 0.5 μg/kg/hr evoked a response during control tests, with the peak output at 32 μg/kg/hr. In animals with denervated pouches, the acid output steadily increased with histamine and peaked at either 160 or 320 μg/kg/hr. There was a significant increase in acid sensitivity to high doses of pentagastrin, and the peak was achieved with 8 μg/kg/hr after denervation. In dogs with denervated pouches, vagotomy produced a highly significant increase in maximal acid output following histamine and pentagastrin. Vagotomy did not increase the secretory effect in dogs with innervated pouches. It is not possible to postulate a single mechanism to account for these results, but they are in keeping with the view that the vagal innervation of the stomach has an inhibitory, as well as a stimulatory, role in gastric secretion.

SECRETION AND METABOLISM

Stomach

0078 CHANGES IN MUCOSAL AND VENOUS HISTAMINE CONCENTRATIONS DURING INSTILLATION OF ETHANOL IN THE CANINE STOMACH. (Eng.) Dinoso, V. P., Jr.; Chuang, J.; Murthy, S. N. S. (Hahnemann Medical Coll. and Hosp., 230 North Broad St., Philadelphia, PA 19102). *Am. J. Dig. Dis.* 21(2):93-97; 1976.

Histamine concentrations in the gastric mucosa, gastric venous blood, and gastric contents were measured after the instillation of 300 ml of 40%, 20%, and 12.5% (volume/volume) ethanol intragastrically for 30 min in anesthetized mongrel dogs. The mean histamine concentration in all areas in dogs treated with 40% ethanol was significantly higher ($p<0.05$) than in dogs treated with NaCl. Serial studies of the gastric venous blood of the ethanol-treated dogs showed significant elevations of histamine concentrations for 2 hr after instillation of 40% ethanol ($p<0.05$). There was less of an increase at 20 and 30 min after instillation of 12.5% and 20% ethanol, resp. The mean concentrations of histamine in the gastric contents of the NaCl-treated dogs and in those treated with 40% ethanol were 0.2 μg/ml and 0.92 μg/ml, resp. No change was observed after administration of 50% glucose and 25% mannitol. Morphologically, the gastric mucosa of the ethanol-treated dogs was edematous, congested, and hemorrhagic. The severity of these changes increased with the concentration used. The results indicate that topical application of 40% ethanol increases the concentration of histamine in the gastric mucosa. However, the precise role of histamine in the pathogenesis of ethanol-induced mucosal damage requires further study.

0079 A COMPARISON OF THE PEPSIN STIMULATING EFFECTS OF SECRETIN PREPARATIONS. (Eng.) Braganza, J. M.; Howat, H. T.; Kay, G. H. (Manchester Royal Infirmary, Manchester M13 9WL, England). *J. Physiol. (Lond.)* 258(1):63-72; 1976.

The peptic responses to Boots, GIH, and synthetic secretins were compared in fasting anesthetized cats in which the pylorus and bile duct were occluded to prevent the release of duodenal hormones by acid and bile salts. A quantity of dilute acid introduced into the stomach at regular intervals ensured the total recovery of viscid secretions and preserved peptic activity. Boots secretin was infused in doses of 2, 4, 8, 16, and 32 Crick, Harper, Raper (C.H.R.) U/kg/hr, while the doses of GIH were 0.5, 1, 2, 4, 8, and 16 clinical units (C.U)/kg/hr. The mean output of pepsin obtained in response to Boots secretin (8 and 16 C.H.R. U/kg/hr) was significantly greater ($p<0.02$ and $p<0.01$, resp.), than the mean pepsin output obtained in response to GIH secretin, (2 and 4 C.U./kg/hr, resp.). The observed maximal peptic response to Boots secretin (16 C.H.R. U/kg/hr) was three times greater than the observed maximal response to GIH secretin (16 C.U./kg/hr). Atropine sulfate (1 mg/kg, i.v.) did not inhibit the peptic response. Synthetic secretin in doses of 4 C.U./kg/hr, GIH secretin 4 C.U./kg/hr and GIH secretin 4 C.U./kg/hr together with cholic acid 0.8 mg/kg/hr, and Boots secretin 16 C.H.R. U/kg/hr, were infused successively. The output of pancreatic juice and lipase remained constant throughout. However, the output of pepsin increased sharply to 800 U/15 min when Boots secretin was given, and the output of acid increased by approximately 100 μEq/15 min. The possibility that a vasodilator substance is present in Boots secretin, which by expanding the splanchnic bed increases the concentration of secretin at target sites in the stomach and pancreas, seems unlikely, as the flow of pancreatic juice does not increase proportionately with the vast increase in pepsin.

SECRETION AND METABOLISM

Hepatobiliary Tract

119 THE ENZYMIC ISOLATION OF ADULT RAT HEPA-
TOCYTES IN A FUNCTIONAL AND VIABLE STATE.
Eng.) Fry, J. R.; Jones, C. A.; Wiebkin, P.;
ellemann, P.; Bridges, J. W. (Dept. Biochemistry,
niv. Surrey, Guildford, Surrey GU2 5XH, England).
nal. Biochem. 71(2):341-350; 1976.

procedure for the enzymic isolation of adult rat
epatocytes in a functional and viable state was
eveloped. Cell suspensions from male Wistar rats
ere prepared by a nonperfusion collagenase/hyaluro-
idase digestion using a sequential removal and
eplacement of Ca^{2+}. An initial Ca^{2+}-removal stage
as incorporated prior to incubation of the liver
lices in Ca^{2+}-containing collagenase/hyaluronidase
olution that enhanced the cell yield and viability
ndex of the resulting cell suspension. All perfu-
ion steps are omitted, which makes the technique
otentially useful with isolated human liver biopsy
aterial. The cell suspensions contained a large
umber of hepatocytes, the majority (>70%) of which
ere viable. The optimal collagenase concentration
or cell isolation was approximately 70 U/ml of
ncubation mixture. A number of liver-specific
unctions were tested for in these cell suspensions.
ne hepatocytes possessed an endogenous glycogenoly-
ic capability, and the rate of glycogenolysis
as stimulated by 3.9 μg/ml glucagon. These hepa-
ocytes are also capable of dealkylating 7-ethoxy-
oumarin, whether or not NADPH is added. The results
now that it is possible to maintain these isolated
epatocytes in a functional state in monolayer
cultures. Preliminary studies have also shown that the method can be applied successfully to hamster, rabbit, ferret, and fetal and adult human liver tissue with a viability of over 90% in each instance.

0120 LIVER CELL CULTURE TOXICITY OF GENERAL ANESTHETICS. (Eng.) Goto, Y.; Dujovne, C. A.; Shoeman, D. W.; Arakawa, K. (Tokyo Medical Coll., Tokyo, Japan). *Toxicol. Appl. Pharmacol.* 36(1):121-130; 1976.

The cytotoxicity of varying concentrations of three anesthetic agents, ethyl ether (E), halothane (H), and methoxyflurane (MF), and of an investigational agent, isoflurane (IF), on Chang cell cultures grown in monolayers was investigated. Loss of intracellular enzymes into the surrounding media was used to quantitate the cytotoxic effects. Drug concentrations in cells and media were monitored during the experiments. Dose- and concentration-related cytotoxic effects were evident for all drugs. Cell cultures were exposed to the anesthetics at doses of 1.0 or 1.5 μl/ml of media, for 5 hr. The greatest leakage of LDH and β-glucuronidase (BG) was found after exposure to MF; progressively decreasing enzyme loss was seen in media of cultures exposed to H and IF. Ether exerted the least cytotoxic effect: there was no leakage of LDH, but that of BG was greater than controls. The differences among all drugs were statistically significant ($p<0.01$). Cells exposed to MF lost over 98% of their LDH and over 50% of their BG into surrounding media. Control cells lost only 20% LDH and 7.5% BG. The comparative *in vitro* effects of the drugs on liver cells seem to correlate with their hepatotoxic potentials in man. The findings suggest that an additional direct, dose-related toxic effect on hepatocellular membranes may play a role in the seemingly hypersensitivity-type of hepatotoxic reactions to halogenated anesthetics.

0121 INFLUENCE OF PHOSPHOLIPIDS ON LIVER DAMAGE. II. CHANGES IN LIPID CONTENT AND SYNTHESIS AFTER LIVER DAMAGE WITH CARBONTETRACHLORIDE [sic] AND OTHER AGENTS.

(Eng.) Bartsch, G. G.; Gerber, G. B. (Div. Medical Chemistry, A. Nattermann GmbH Cologne, W. Germany). *Acta Hepatogastroenterol.* 22(4):228-236; 1975.

The liver lipid content, incorporation of acetate into hepatic lipids, and hepatic DNA synthesis were studied in normal x-irradiated (2 kr of whole-body irradiation) and partially hepatectomized male Wistar rats and male BALB/c$^+$ mice. The animals were first treated with CCl_4 (0.25 ml to rats and 0.05 ml to mice by stomach tube), and an essential phospholipid (EPL) phosphatidylcholine (1 ml of a 10% aqueous suspension in rats and 0.2 ml in mice, i.p. for 7 days prior to CCl_4 treatment), and/or orotic acid (1% of the diet). 6-^{3}H-thymidine (100 µCi) and acetate 1-^{14}C (5 µCi) were injected i.p. 1 hr before sacrifice. EPL treatment caused no marked change in the hepatic lipid composition of the normal rats or mice. CCl_4 poisoning produced an increase in the lipid content that was observable at 6 hr, more marked at 24 hr, and still noticeable after 7 days. The increase was primarily due to an augmentation of neutral lipids, the phospholipid content being unaltered or slightly decreased. Pretreatment with EPL for 7 days prior to CCl_4 administration significantly decreased the effect of the latter on the hepatic lipid content at 24 hr; the effect was less marked at 6 hr. EPL given as a single injection at the time of CCl_4 treatment had a similar, but less marked, effect. In rats treated with EPL for 7 days following CCl_4 administration, the liver lipid levels returned to normal more rapidly than after CCl_4 treatment alone. CCl_4 poisoning elevated the incorporation of acetate-1-^{14}C into the liver phospholipids, triglycerides, cholesterol, and cholesterol esters, but not the incorporation into total lipids. EPL pretreatment slightly increased the incorporation into triglycerides and phosphatidylcholine. Orotic acid increased all liver lipids in the rat, but not in the mouse; EPL treatment was only slightly beneficial in decreasing this effect. During liver regeneration, the total lipids and, in the rats, the phospholipids increased significantly, and the ratio of neutral lipids to phospholipids was greater than normal; EPL had no effect on this increase. The DNA content of the liver was slightly diminished after EPL treatment, and the increased incorporation of thymidine into the liver DNA during regeneration was further increased by EPL. The inhibition of regeneration caused by whole-body x-irradiation was not influenced by EPL. EPL increased the content and synthesis of thymic DNA in x-irradiated rats, but had no effect on the x-ray-induced depression in intestinal DNA synthesis. The results suggest that phospholipids may prevent the formation or induce the degradation of the hypothetical toxic radical formed by homolytic cleavage of the C-Cl bond in CCl_4 poisoning.

0122 HEPATIC LIPID LEVELS IN INTACT AND THYROIDECTOMIZED RATS FOLLOWING ADMINISTRATION OF TETRACYCLINE OR ETHANOL.

(Fre.) Chaibi, A.; Clement-Champougny, J. (Equipe de Recherche du C.N.R.S. No. 188, U.E.R. Nutrition, Universite de Dijon, Faculte des Sciences Mirande, Campus universitaire, 21000 Dijon, France). *Arch. Int. Physiol. Biochim.* 83(3): 535-552; 1975.

The results of thyroidectomy on hepatic lipids in rats after tetracycline or ethanol administration were examined. Three experiments were conducted in both thyroidectomized and intact rats: to determine the effect of tetracycline (TCL) on animals fed a commercial 6% fat and 17% protein diet (I); to determine the effect of a single dose of ethanol on rats receiving 6% or 19% fat feedings (II); and to measure the effect of ingesting ethanol and 19% lipids for 5 months (III). Female Sprague-Dawley rats were used for I and II, male Wistar rats were used for III. Thyroidectomy was performed 3 weeks prior to testing. In I, TCL was given ip in two injections of 160 mg/kg at 16-hr intervals. In II, ethanol (5 g/kg) was given by gavage. In III, 5%, 10%, 15%, and 20% solutions, each separated by 2 weeks, were given instead of water for 5 months. In thyroidectomized rats, there were significant reductions in total lipids (TL), phospholipids (PL), nonphosphorylated lipids (NPL), and total cholesterol (CH). In a gram of fresh liver, the differences between homologous groups, intact or thyroidectomized, were insignificant with the commercial diet. A conspicuous steatosis developed (NPL x 1.6) in thyroidectomized and normal rats on the semisynthetic diet. TCL led to acute steatosis in normal and thyroidectomized rats, with elevated NPL (3x), TL, and CH levels. The ethanol effect varied directly with the fat composition of the diet. Chronic alcoholism elicited diminished TL and NPL levels in intact and thyroidectomized rats. Relative to dietary lipids, alcohol had no effect on intact animals. The CH level was increased in thyroidectomized animals on semisynthetic diets over that in normal rats. Thyroid removal reduced the free fatty acid in plasma in both feeding and fasting animals and the triglyceride levels in feeding, but not fasting, rats. TCL was without effect on the free fatty acids of intact rats.

0123 HEPATOCYTE VACUOLATION AND INCREASED LIVER WEIGHT OCCURRING IN ANOXIC RATS.

(Eng.) Sykes, B. I.; Penny, E.; Purchase, I. F. H. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Cheshire SK10 4TJ, England). *Toxicol. Appl. Pharmacol.* 36(1):31-39; 1976.

The postmortem conditions under which hepatocyte acuolation and increased liver weight occur in noxic rats were investigated in Alderley Park istar-derived rats. The rats were killed in a -liter jar to which halothane (25 ml) or other nesthetics were added. The length of time the ats remained in the jar varied. Vacuolation ccurred when rats were killed in 10% halothane aporized in an 80% nitrogen/20% oxygen mixture nd left for 3 min before removal of the liver. f the anesthetic was vaporized in a decreasing ercentage of O_2 in N_2, the incidence of vacuolation ncreased. Slight vacuolation occurred in animals illed separated by halothane who were left as ong as 3 min after cessation of breathing before eing bled by cardiac puncture. Volatile anesthetics chloroform, ether, and methoxyflurane) used in closed jar and an i.p. injection of sodium pento- arbital produced hepatocyte vacuolation. Extensive acuolation occurred in rats killed with N_2 who ere left 5 min before removal of the liver. levated liver/body weight ratios were associated ith vacuolation. It is concluded that the hepa- ocyte vacuolation sometimes observed in rats at ecropsy is associated with anoxia, with vacuolation eveloping after death. When breathing ceases, ew vacuoles are seen unless the animals are killed n anoxic conditions. After death, considerable acuolation develops within a few minutes, but if he animal is bled at the time breathing ceases, he vacuoles do not appear.

124 PROTEIN SYNTHESIS IN LIVER INJURY. SOLUBLE FACTORS OF PROTEIN SYNTHESIS IN THE CYTO- OL FROM ISCHEMIC RAT LIVER. (Eng.) Cajone, F.; chiaffonati, L.; Bernelli-Zazzera, A. (Istituto di atologia Generale, Centro di Patologia Cellulare el CNR, Universita degli Studi di Milano, 20133 ilan, Italy). *Lab. Invest.* 34(4):387-393; 1976.

he soluble factors of protein synthesis contained the cell sap from ischemic livers was investigated male Wistar rats. The high-speed supernatant cell sap) was obtained from the supernatant of schemic liver homogenates. This cell sap was less fficient than that from normal liver in supporting rotein synthesis in cell-free systems. Cell saps rom 120-min ischemic livers contained a reduced mount of transfer RNA (tRNA); the transfer of ^{14}C- eucine to the specific tRNA was impaired; and the ncorporation of leucyl-tRNA into protein was educed, although less than the incorporation of he corresponding amino acid. In a typical experiment, ncorporation in the presence of 120-min ischemic I 5 supernatant amounted to 90,500 counts per min cpm)/mg ribosomal RNA (rRNA) compared to 181,400 pm/mg rRNA attained by the normal cell sap. In ddition, the binding of aminoacyl-tRNA to ribosomal ubunits (40S and 60S) and exogenous messengers polyuridylic acid and uridyl-3',-5'-uridyl-3',-5' guanosine) was less efficient with ischemic than ith normal cell sap, indicating a defective activ- ty of elongation factor 1. The total amount, nd possibly the intracellular distribution, of longation factor 2 was also altered in ischemic ivers. These changes, which are the expression f a multifunctional deficit of ischemic cell sap, re, in general, correlated with the duration of ischemia and do not seem to appear around the "point of no return" of the ischemic liver cells.

SECRETION AND METABOLISM

Intestine

0172 LYSOSOMES IN THE EPITHELIUM OF THE INTESTINE. A DEVELOPMENTAL INVESTIGATION. (Ger.) Gossrau, R. (Anatomisches Institut der Universitat Wurzburg, Koellikerstr. 6, 8700 Wurzburg, W. Germany). *Adv. Anat. Embryol. Cell Biol.* 51(5): 1-92; 1975.

The hormonal status, light microscopic, and ultrastructural histochemistry of pre- and postnatal lysosome (LYS) development in rat gut epithelium were explored. Four discrete functional periods were identified. Beginning with gestation day 15 and ending on postnatal day 1, there is a rapid proliferation of simple columnar epithelium without LYS activity. During subsequent epithelial stratification, LYS and its enzymatic components (acid phosphatase, *N*-acetyl-β-glucosaminidase, α-galactosidase, β-glucuronidase, α-mannosidase, acid β-galactosidase, and carboxylesterases) become actively involved in the transformation of the primitive to the resorptive epithelium. The LYS enzymes appear on gestation day 16 on the luminal side of the epithelium, and only later in the deeper layers of the stratification. The regression of stratification is characterized principally by cell death, which leads to cleft formation, and autophagy, which leads to primary villi formation. By gestation day 18, mesenchyme has infiltrated the villi, and the secondary villi are formed, simultaneous with differentiation of the resorptive epithelium. Cell death is not characteristic of the outer epithelial layer where lysosomes are produced by the endoplasmic reticulum. The basal LYS fuses into the first generation of giant LYS, concurrent with their displacement into the apical cytoplasm and secondary villi formation, especially in the distal gut. Acid hydrolase activity continues to increase distally, while proximal activity develops fully only 2 days prenatally. Regional differences are already established in the gut before birth. Digestive function also begins immediately prenatally, although full enterocyte function develops only postnatally. Distally, the villous membrane system enlarges and the LYS enzymes increase for the second time. Proximally, the enterocytes absorb most of the maternal milk fat. Shortly after onset of the second developmental period (postnatal days 1-23), the gut epithelium is fully functional. The lipids pass the cell via Golgi and endoplasmic reticular intervention, although the number and structure of villi relate to the amount of fat absorbed. The villi are interpreted as transient structures enlarging the cell surface. The proximal, but not the distal, enterocytes ingest maternal antibodies by phagosomes. In the distal giant LYS, 13 different hydrolases can be demonstrated, concurrent with microvillous membrane differentiation for protein transport from maternal milk. Eventually, the enterocytes of the luminal surface ingest macromolecules exclusively. It is believed that disaccharides and peptides are preferentially hydrolyzed in the proximal gut. The third, or retrogression, period extends from day 17 to day 23. LYS enzymatic activity and lactase decreases distally and maltase increases proximally. During the fourth period, beginning at 23 days, all proximal enterocytes with coated vesicles and all distal enterocytes containing giant LYS are replaced by adult absorptive epithelium without the organelle system. The period of regional differentiation is probably controlled by carbohydrate ingestion from maternal milk. Early postnatal adrenal immaturity is thought to ensure that the regional enterocyte differentiation is not prematurely destroyed by formation of adult columnar epithelium.

173 AUGMENTATION OF ETHANOL ABSORPTION BY MONO-
AND DISACCHARIDES. (Eng.) Broitman, S.
.; Gottlieb, L. S.; Vitale, J. J. (Boston Univ. Sch.
edicine, Boston, MA 02118). *Gastroenterology* 70(6):
101-1107; 1976.

he effects of various carbohydrates on the intestinal
bsorption of ethanol were studied in Charles River
ats using a small bowel perfusion system. Fructose,
-*O*-methyl-glucose, glucose, galactose, lactose,
ucrose, and maltose were each added at 50 mM con-
entrations to perfusates containing 50 mM ethanol and
% polyethylene glycol. Perfusates were pumped
hrough the small bowel at 1.5 ml/min, and samples
ere collected at 10-min intervals for 1 hr. From a
ontrol value of 2.45 mmol of ethanol absorbed per
our per animal, glucose, sucrose, galactose, and
altose augmented ethanol absorption from 18 to 33%;
lthough values obtained with these sugars were sig-
ificantly different from those of controls (p<
.005). Only the value obtained with maltose was
ignificantly ($p<0.005$) different from that of the
ther three carbohydrates. Only galactose increased
lood ethanol levels above control values. The cor-
elation coefficient 0.94 ($p<0.01$), expressing the
elation of augmentation of ethanol absorption to the
uantity of water absorbed or lost (net water flux)
uring the perfusion of ethanol with various carbo-
ydrates, implied that the ability of the various car-
ohydrates to augment ethanol absorption is related
o the ability of that sugar to promote water ab-
orption. Addition of maltose (2-25 mM) to an ethanol
erfusate augmented ethanol absorption in a direct
roportion to the quantity of glucose absorbed,
ather than to the quantity of maltose hydrolyzed.
he results suggest that augmentation of ethanol ab-
orption by carbohydrates appears to be dependent
pon sugar-active transport.

174 HISTOCHEMICAL STUDIES ON FAT ABSORPTION IN
THE JEJUNAL MUCOSA AFTER TOTAL PANCREATEC-
OMY IN DOG. (Eng.) Yoshizawa, Y.; Mizumoto, R.;
akase, A.; Honjo, I. (115-Okamachi, Moriyama City,
higa, Japan). *Am. J. Surg.* 131(6):689-696; 1976.

istological and histochemical changes in the jejunal
ucosa were investigated to clarify the pathogenesis
f the disturbances of digestion and absorption and
he effect of estrogen on absorption after total
ancreatectomy in dogs. The crypts of Lieberkuhn
n the jejunal mucosa were slightly lengthened, but
decrease in the absorptive surface due to villous
trophy was not observed, after total pancreatectomy.
he jejunal epithelium contained little or no Sudan-
ositive material in normal 24-hr-fasted dogs, but
ipid droplets stained with Sudan III were sometimes
ound in the absorptive epithelium, and occasionally
n the central lacteals, in pancreatectomized dogs
reated with insulin alone (0.5-1.0 U/kg). When
stradiol benzoate (1,000 U/kg) was administered
ogether with insulin, lipid droplets were not ob-
erved in the epithelial cells or central lacteals,
s in control dogs. After p.o. administration of
live oil or oleic acid (1.5 ml/kg each), absorbed
ipid droplets were not observed in the jejunal
ucosa of dogs treated with insulin alone after total pancreatectomy. When estrogen was administered together with insulin, numerous lipid droplets appeared in the jejunal mucosa after p.o. administration of oleic acid, although olive oil was not absorbed. ATP, alkaline phosphatase, and succinic dehydrogenase activity decreased markedly in the absorptive epithelium in dogs treated with insulin alone after total pancreatectomy. Activity returned to normal after the addition of estrogen. The results show that there is a definite impairment in fat absorption after total pancreatectomy, which can be attributed to the decreased activity in the epithelium of enzymes such as ATP, alkaline phosphatase, and succinic dehydrogenase. The activity of these enzymes can be restored by estrogen administration, which is then accompanied by an improvement in fatty acid absorption.

GENERAL

0193 SUPERIOR MESENTERIC ARTERY OCCLUSION IN DOGS: A MODEL TO PRODUCE THE SPECTRUM OF INTESTINAL ISCHEMIA. (Eng.) Bonakdarpour, A.; Ming, S.; Lynch, P. R.; Essa, N.; Reichle, F. (Temple Univ. Sch. Medicine, 3401 N. Broad St., Philadelphia, PA 19140). *J. Surg. Res.* 19(4):251-257; 1975.

A surgical model in dogs that can reliably simulate the spectrum of changes seen in intestinal ischemia in man by varying the length and extent of ischemic bowel is presented. Ischemia of a precise segment of bowel was produced in 36 mongrels by ligation and transectio of a branch of the superior mesenteric artery. Bowel ischemia of 15-60 cm was produced in 11 dogs; none died. No gross abnormalities were present in any of the dogs. Bowel ischemia of 65-105 cm was produced i 11 dogs; none died. Three dogs sacrificed 1-2 months after operation showed focal mucosal atrophy and submucosal fibrosis. Bowel ischemia of 110-200 cm was produced in 14 dogs; 7 died within 2 days and 3 died

ithin 6 days. Hemorrhagic necrosis of the mucosa was
ommon in the regions peripheral to areas of total in-
arction. The remaining dog had bowel ischemia of
17 cm and showed multiple linear ulcerations in the
schemic segment, with infarction. It is concluded
hat this easily reproducible model can reliably be
sed to study the various stages of intestinal ische-
ia from mildly decreased perfusion to complete in-
arction of the intestine.

194 EXPERIMENTAL XENOGENIC IMMUNE PANCREA-
TITIS. IMMUNOHISTOLOGICAL, ENZYME HISTO-
HEMICAL AND ULTRASTRUCTURAL STUDIES. (Ger.) Nizze,

es Bereichs Medizin der Universitat Rostock, Strem-
elstrasse 14, DDR-25 Rostock 1, E. Germany). *Exp.
athol. (Jena)* 11(5/6):219-232; 1975.

orphological and enzymatic alteration in exocrine
ouse pancreas (MP) after challenge by xenogenic
mmune MP antiserum was analyzed. The test groups
ncluded 24 mice challenged with anti-MP rabbit
erum (group A), 12 with normal rabbit serum (group
), 12 with physiological salt solution (group C),
nd 6 untreated mice. Group A-C received 1, 3, 5,
, 17, or 33 injections, i.p., of 0.3 ml serum or
aline, either at 3 hr or 1, 2, 4, 6, 8, or 16 days.
ancreatic sections were also incubated with
nlabeled anti-rabbit globulin goat serum (ARGS) for
nzyme histochemistry. In group A, a chronic
clerotic pancreatitis appeared, with acinar necroses
nd eosinophil and neutrophil infiltration on days
, 3, and 5 and interstitial lymphocyte, histiocyte,
nd plasma cell inflammation on days 9 and 17.
fter incubation with ARGS, the fluorescence was
educed and restricted to the serosa, which by day
5 reached the acinar basal membranes, indicating
abbit globulin. Nonspecific esterase, acid phos-
hatase, and lipase activity was slight to marked
rom day 1 to day 16, peaking on day 4. Succinic
ehydrogenase, cytochrome oxidase, ATPase, and
lkaline phosphatase were either absent or negligible.
ne enzymatic concentration corresponded temporally
o the granulating lymphoreticular pancreatitis
naracteristic of delayed-type allergic response.

195 EXPERIMENTAL FOREIGN SERUM PANCREATITIS.
HISTOLOGICAL AND HISTOCHEMICAL FINDINGS
N THE EXOCRINE PANCREAS OF THE MOUSE FOLLOWING
EPEATED INTRAPERITONEAL INJECTIONS OF SERUM OF
THER SPECIES. (Ger.) Nizze, H. (Institut fur
llgemeine und Spezielle Pathologie, Universitat
ostock, DDR-25 Rostock 1, Strempelstrasse 14,
. Germany). *Zentralbl. Allg. Pathol.* 119(4):294-
02; 1975.

istological and enzymatic modification of mouse
xocrine pancreas by sera from heterologous species
s described. The test sample included challenge
y bovine serum (A), horse serum (B), human serum
C), rabbit serum (D), pooled AB-mouse serum (E),
nd physiologic salt soltion (F). I.p. injections
ere made at 3 hr or twice daily on days 1, 2, 4,
, or 16. Groups A-D showed interstitial edema
nd marked subperitoneal-perivascular granulocytosis
eosinophils, neutrophils) in the first days. After
day 5, and peaking at days 9 and 17, there was lymphocytic, histiocytic, and plasma cell accumulation and maximum activity for acid and alkaline phosphatases and nonspecific esterase. Negligible interstitial fibrosis and slight acinar dystrophy was apparent only in group A, which elicited more prominent responses than the other groups for all histological and histochemical variables. Repeated inoculation is believed to trigger delayed allergic, serum-sickness type responses.

GASTROINTESTINAL DISEASES

ESOPHAGUS

0292 VALUE OF CRICOPHARYNGEAL MYOTOMY AND OF DISSECTION OF THE SUPERIOR FIBERS OF THE ESOPHAGUS IN PHARYNGEO-ESOPHAGEAL DYSKINESIA. REPORT OF SEVEN CASES. (Fre.) Desaulty, A.: Piquet, J. J.; Vaneecloo, F. M.; Decroix, G. (Centre Hospitalier Regional, service O.R.L., Place Verdun, 59000 Lille, France). *J. Fr. Otorhinolaryngol.* 24(7):527-533; 1975.

Sectioning of the cricopharyngeal muscle by extramucosal myotomy in seven patients with pharyngeo-esophageal dyskinesia and deglutition dysfunction is reported. In three cases, there was a traumatic vascular or degenerative cause of the pharyngeal paralysis. In two other cases, there was progressive secondary stenosis and modification of the cricopharyngeal muscle, in part isolated (myopathy) and in part associated with degenerative nerve termini (achalasia). One patient presented with idiopathic vertebrobasilar insufficiency with syncopal attacks. There was severe persistent dysphagia in these six cases. In the seventh patient, a pharyngeal paresthesia in a dystonic context could not be modified surgically. In cricopharyngeal section, the incision is made at the anterior edge of the sternocleidomastoid muscle, usually on the left. The sternocleidomastoid is retracted, the omohyoid sectioned, and the inferior thyroid artery and vein ligated. The cricopharyngeal is then sectioned posterior to the cricoid insertion. The muscle fibers surrounding the upper part of the esophagus are also sectioned. Endoscopy is required to confirm complete sectioning of all fibers.

0293 COMPLICATIONS OF VAGOTOMY IN THE TREATMENT OF HIATAL HERNIA. (Eng.) Vansant, J. H.; Baker, J. W., Jr. (Eastern Virginia Medical Sch., Norfolk, VA). *Ann. Surg.* 183(6):629-635; 1976.

The morbidity of vagotomy in the treatment of reflux esophagitis was evaluated in a retrospective study of 311 patients treated by the Hill posterior gastropexy technique of hiatal hernia repair. Vagotomy with antireflux operation was performed on 159 patients (51%); vagotomy was not included for 152 patients (49%). The incidence of postoperative symptoms with or without vagotomy was almost equally divided--64 (41%) without vagotomy and 74 (47%) with vagotomy. The major postoperative symptoms occurring in both groups were abdominal cramps and bloating in 116 patients (37%), which usually disappeared in the early postoperative period and were attributed to the anti-reflux procedure and not to vagotomy. Diarrhea occurred in 26 patients (17%) without vagotomy and in 54 (34%) with vagotomy. Nausea and vomiting occurred in only 2 patients (1%) without vagotomy, but in 20 (13%) with vagotomy. Dumping only occurred in 11 patients with vagotomy (7%). Long-term postoperative symptoms, judged on the basis of symptoms of 3-months' duration, occurred in 1% of patients without vagotomy and in 26% of patients with vagotomy. This study reveals that no additional protection against recurrent symptoms of gastroesophageal reflux or radiographic evidence of recurrent hiatal hernia was provided by inclusion of vagotomy. It is concluded that vagotomy is contraindicated in the treatment of gastroesophageal reflux, except in the presence of peptic ulcer disease.

0294 ENDOSCOPIC SIGNS FOR GASTROESOPHAGEAL REFLUX OBJECTIVELY EVALUATED. (Eng.) Johnson, L. F.; DeMeester, T. R.; Haggitt, R. C. (Walter Reed Army Medical Center, Washington, DC 20012). *Gastrointest. Endosc.* 22(3):151-155; 1976.

Esophagoscopic findings were evaluated in 76 patients with competent (24) and incompetent (52) esophagogastric junctions, objectively demonstrated by distal esophageal sphincter (DES) pressure, the standard acid pH reflux test (SART), and 24-hr monitoring 5 cm above the DES for pH 4. Esophagoscopy was performed in all patients, and endoscopic interpretations were recorded before infusion manometry, SART, and 24-hr pH monitoring. The abnormal reflux group had a lower mean DES pressure (12 mm Hg versus 22 mm Hg, $p<0.001$) and more radiographic reflux (52% versus 17%, $p<0.01$) than the normal reflux group. The dista esophageal mucosa appeared to be normal in 46% of the abnormal reflux group, while 12% of the normal reflux group had an endoscopic appearance of esophagitis. These patients were very heavy cigarette smokers (mean age of 37 yr, a 57 mean pack-yr history of smoking). Papillary length in biopsy specimens was comparable in both smokers and nonsmokers in the abnormal reflux group, while smokers in the normal reflux group had longer papillae ($p<0.02$) than nonsmokers. In comparison to the normal reflux group, the abnormal reflux group more often had hiatal hernias (81% versus 21%, $p<0.005$), patulous diaphragmatic hiatus (52% versus 8%, $p<0.005$), and gastric rugal hypertrophy (13% versus 0%, not significant) in the area of the esophagogastric junction. The endoscopic diagnosis of hiatal hernia combined with either endoscopic esophagitis or patulous diaphragmatic hiatus accurately predicted abnormal reflux in over 90% of the patients. Macroscopic esophagitis and histologic esophagitis are of limited usefulness in cigarette smokers for determining the state of esophagogastric junction competency; endoscopic assessment of esophagogastric junction competence is improved by combined diagnoses.

0314 GASTRIC CHEMODECTOMA: A STUDY OF ONE CASE AND A REVIEW OF THE LITERATURE. (Fre.) Delamarre, J.; Potet, F.; Capron, J. P.; Hoang Ngoc Minh; Lorriaux, A. (Clinique Medicale A, Centre Hospitalier Universitaire, place Victor-Pauchet, F 80030 Amiens Cedex, France). *Arch. Fr. Mal. App. Dig.* 64(4):339-346; 1975.

The case history of chemodectoma in a 49-yr-old man is presented, and the literature is reviewed. The patient had a history of phenylbutazone and indomethacine management of rheumatoid arthritis and presented with gastrointestinal bleeding. Clinical, radiological, and paraclinical tests were negative, but gastroscopy detected a sessile antral mass with normal mucosa. At intervention, a round elastic tumor embedded in the posterior was excised. Histologically, it was located in the submucosa, with moderate muscularis invasion. Part of the mass was lobulated, with foci of hemorrhagic necrosis. The weakly eosinophilic, voluminous cells had assumed an alveolar arrangement, and neural fibers had proliferated. Final diagnosis was that of a local, probably malignant, chemodectoma. The patient has remained tumor-free for 5 yr. Because of the slow development of the tumor and the ineffectiveness of radiotherapy, tumor resection is the method of choice.

0315 THE NONOPERATIVE TREATMENT OF MASSIVE PYLORODUODENAL HEMORRHAGE BY RETRACTED AUTOLOGOUS CLOT EMBOLIZATION. (Eng.) Eisenberg, H.; Steer, M. L. (Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215). *Surgery* 79(4):414-420; 1976.

The nonoperative treatment of massive pyloroduodenal hemorrhage by retracted autologous clot embolization is described in six patients who had severe associated illnesses and were very poor candidates for surgical treatment. Bleeding was effectively controlled in five patients. The previously bloody nasogastric aspirate cleared, and the patients' vital signs stabilized. Two patients later experienced bleeding from other sources. Although three patients died, none died as a direct result of bleeding. The only complication encountered, multiple small hepatic infarcts, occurred when the embolized clot migrated from the gastroduodenal artery to the hepatic artery. This was a consequence of the bidirectional nature of gastroduodenal arterial flow; migration can be avoided by eliminating retrograde gastroduodenal arterial flow with a balloon prior to injection of the clot. Selective embolization of retracted autologous clot represents a useful alternative to the surgical management of massive pyloroduodenal hemorrhage and should be considered for the treatment of patients whose associated diseases make them poor candidates for surgical treatment.

STOMACH

Peptic Ulcers

0356 THE RELATION BETWEEN FUNCTIONING PARIETAL CELL AND GASTRIN CELL MASSES IN TWO GROUPS OF DUODENAL ULCER PATIENTS. (Eng.) Byrnes, D. J.; Lam, S. K.; Sircus, W. (St. Vincent's Hosp., Darlinghurst, Australia). *Clin. Sci. Mol. Med.* 50(5):375-383; 1976.

Serum gastrin concentrations were determined befor and after a standardized meal in 28 patients with duodenal ulcer and in 10 normal control subjects t correlate the relation between functioning parieta cell and gastrin cell masses. All ulcer patients and eight controls received an i.m. injection of

entagastrin (6 μg/kg), and the total acid secretion
or maximum acid output) was collected at 20-min
tervals for 1 hr. Thirteen patients with ulceration
ere normosecretors (mean maximum acid output 0.37 ±
01 mmol/hr/kg) and 15 patients were hypersecretors
.69 ± 0.06 mmol/hr/kg). There was no statistically
gnificant difference between the mean values of
e basal serum gastrin levels of the normal subjects,
e normosecreting duodenal ulcer patients, and the
persecreting duodenal ulcer patients, but the low
lue of the hypersecretors is highly suggestive of
real difference (mean values=75.0, 71.0, and
.0 pg/ml, resp.). The mean integrated gastrin
sponse was significantly higher in normosecretors
an in the normal subjects ($p<0.01$) and the hyper-
cretor patients ($p<0.3$). A significant inverse
rrelation exists between the maximal acid output
d the integrated gastrin response in both normal
bjects and hypersecreting duodenal ulcer patients
<0.05). The results demonstrate that the maximal
id output is an accurate index of the gastric
rietal cell mass.

57 CIMETIDINE INHIBITS CAFFEINE-STIMULATED GASTRIC ACID SECRETION IN MAN. (Eng.)
no, R.; Isenberg, J. I.; Grossman, M. I. (Veterans
min. Wadsworth Hosp. Center, Los Angeles, CA 90073).
stroenterology 70(6):1055-1057; 1976.

e effect of the H_2-receptor antagonist cimetidine
gastric acid secretion stimulated by the methyl
nthine caffeine was examined in five duodenal
cer patients and in five normal subjects. One hour
ter the administration of cimetidine (300 mg, p.o.),
ffeine (9 mg/kg/hr, i.v.) was given for 2 hr. Gas-
c juice was collected at 15-min intervals during
ffeine infusion. The mean basal gastric acid out-
was significantly greater ($p< 0.05$) in the duo-
al ulcer patients than in the normal subjects.
er administration of a placebo, i.v., caffeine
usion produced a significant increase ($p<0.025$)
gastric acid secretion in both duodenal ulcer pa-
nts and in normal subjects. The mean caffeine-
mulated gastric secretion during the second hr of
usion was 40.6 ± 7.3% of maximal gastric acid
retion in the duodenal ulcer group and 15.2 ± 1.5%
the normal group ($p<0.01$). In both groups, cimet-
ne abolished the response to caffeine. During
feine infusion after cimetidine, the mean acid
retory rates in both the duodenal ulcer and normal
ups were less than basal. The results indicate
t cimetidine inhibits caffeine-stimulated gastric
d secretion in man.

8 SLEEP PATTERNS AND GASTRIC ACID SECRETION IN DUODENAL ULCER DISEASE. (Eng.) Orr, W.
Hall, W. H.; Stahl, M. L.; Durkin, M. G.; Whitsett,
L. (Veterans Admin. Hosp. [183], 921 NE 13th St.,
ahoma City, OK 73104). *Arch. Intern. Med.* 136
:665-660; 1976.

possible relation between gastric acid secretion
sleep stages during non-drug induced sleep was
estigated for five consecutive nights in five
mal patients and in five patients with duodenal
er. All subjects underwent placement of a naso-
gastric tube, continuous collection of gastric juice, and continuous electroencephalographic monitoring of sleep. Gastric juice was collected in 20-min samples by remote suction, and blood samples were drawn every 20 min on the third night via an indwelling venous needle. There was no significant correlations between the sleep variables and the gastric acid secretion measures ($p<0.05$) or between the sleep variables and the serum gastrin levels ($p<0.05$). Acid secretion decreased significantly from hour 1 to hour 2 in controls and in patients with inactive duodenal ulcer disease, while it increased in patients wiht active duodenal ulcer disease ($p< 0.02$). Each subject had at least one night of recording in which continuous gastric secretion was less than 0.1 mEq/20 min-sample. It appears unlikely that the gastric discomfort of duodenal ulcer patients can be attributed to acid hypersecretion triggered by rapid eye movement sleep.

SMALL INTESTINE

393 OVERWHELMING WATERY DIARRHEA ASSOCIATED WITH A CRYPTOSPORIDIUM IN AN IMMUNOSUPPRESSED PATIENT. (Eng.) Meisel, J. L.; Perera, D. R.; Meligro, C.; Rubin, C. E. (Group Health Hosp., Dept. Medicine, Univ. Washington, Seattle, WA 98195). *Gastroenterology* 70(6):1156-1160; 1976.

report of intestinal cryptosporidiosis in a 39-yr-old man with severe bullous pemphigoid, who developed overwhelming diarrhea after 5 weeks' treatment with 50 mg of cyclophosphamide and 80 mg of prednisolone daily, is presented. Jejunal and ileal biopsies showed severe mucosal injury, and spherical particles, -4 μ in diameter, were scattered along some epithelial surfaces. These particles appeared to be attached to the brush border of the absorptive cells in the tips and sides of some villi and to the epithelial surface of some crypts. Similar organisms were seen in smears of jejunal fluid. Electron microscopic examination of jejunal bodies showed these spherical organisms to be trophozoites, schizonts, microgametocytes, and macrogametocytes typical of the genus *Cryptosporidium*. Diarrhea resolved 2 weeks after discontinuation of cyclophosphamide and coincided with the disappearance of *Cryptosporidia* from the jejunal biopsies. Immunosuppression may have predisposed this patient to cryptosporidial diarrhea. Cryptosporidiosis is another infection that can be diagnosed by small bowel biopsy. It is concluded that when immunosuppressed patients develop severe diarrhea, opportunistic infection with this and other organisms should be considered as the possible cause.

0436 PROTEIN-DEPLETION ENTEROPATHY AND RETRACTILE MESENTERITIS. (Fre.) Nouel, O.; Eugene, C.; Gislon, J.; Marche, C. (Service de Gastroenterologie B, Hopital Bichat, 170, boulevard Ney, F 75877 Paris Cedex 18, France). *Arch. Fr. Mal. App. Dig.* 64(3):233-238; 1975.

A case history of chylous ascites and exudative enteropathy with retractile mesenteritis is reported. A 62-yr-old man with no medical or surgical history, except 300 ml alcohol/day for 30 yr, presented with edema and ascites, complicating a suspected cirrhosis. The clinical examination was negative. The liver function was normal; the serum proteins were abnormal, but there was no proteinuria; and renal function was normal. The chylous ascites contained 150 lymphocytes/mm^3. Transcutaneous liver biopsy showed portal fibrosis with regenerative nodules. Subsequent confirmation of hypoalbuminemia, hypocalcemia, lymphopenia, hypogammaglobulinemia, and abnormally low serum lipids indicated exudative enteropathy. Jejunal biopsy showed villi of normal structure, but with increased lymphoplasmacytic cellularity, and edema of the lamina propria associated with dilation of the basal intercellular spaces. Exploratory laparotomy found lymph exudation and lymphatic "sacs" of 1- to 2-cm diameter along the mesenteric border of the small bowel and a dense mesentery retracted on itself, measuring 4 cm at the root. All other tissues and spaces, including the mesocolon and retroperitoneum, were normal. A postoperative regimen of medium chain triglycerides was begun. Despite persistent paraclinical signs of enteropathy 10 months postoperatively, the patient's condition is improved. The etiology and absence of recurrences cannot be explained.

LARGE INTESTINE

452 VALUE AND LIMITATIONS OF THE DETERMINATION
OF CARCINOEMBRYONAL ANTIGEN (CEA) IN THE
STOPERATIVE FOLLOW-UP OF PATIENTS WITH CARCINOMA
THE COLON AND RECTUM. (Fre.) Jaeger, Ph.;
ettavel, J.; Wuilleret, B.; Bertholet, M. M.; Mach,
. P. (Institut de biochimie, Universite de Lausanne,
rue du Bugnon, CH-1011 Lausanne, Switzerland).
chweiz. Med. Wochenschr. 105(46):1533-1538; 1975.

ne utility of carcinoembryonic antigen (CEA) levels
evaluating surgical resection for colon carcinoma
nd in postoperative follow-ups is explored. The
linical sample included 101 cases of colorectal carcinoma, 71% of whom had CEA levels equal to or greater than 5 ng/ml. In 45 cases, the CEA levels were consistently below 5 ng/ml 2-4 weeks after resection, while 5 cases presented progressive elevations and were subsequently found to have tumor recurrences. In 19 patients with remote metastases or partial resection, the CEA levels showed a wide scatter, which could not be interpreted prognostically. Follow-ups of 22 of 45 patients with total resection whose preoperative levels were above 2.5 ng/ml, found that 14 had borderline normal or values below 5 ng/ml for up to 27 months postoperatively. Eight showed progressive elevations in CEA for 2-10 months before the tumor recurrence became clinically obvious.

0453 ANO-RECTAL TUBERCULOSIS SIMULATING CARCINOMA. (Eng.) Gupta, A. S.; Sharma, V. P.; Rathi, G. L. (R. N. T. Medical Coll., Udaipur, India). *Am. J. Proctol.* 27(1):33-38; 1976.

Five cases of anorectal tuberculosis, which were all originally diagnosed as rectal cancer, are presented. There were three women and two men, ranging in age between 20 and 45 yr. The first patient presented with rectal pain and bleeding; the second patient with bleeding, pain, and constipation; the third patient with bleeding and constipation; the fourth patient with diarrhea, passage of blood and mucus per rectum, and weight loss; and the fifth patient, with itching and ulceration at the anal verge, anorexia, and weight loss. The symptoms had been present for 6 months to 1.5 yr. The lesions in the first four patients occurred 5-8 cm above the anus; in the fifth patient, the ulcer was perianal and extended into the anal canal. The lesions ranged between 4 x 3 cm and 6 x 4 cm, and were ulcerating in patients two and five. The diagnosis of anorectal tuberculosis was made by biopsy of the lesion in all cases. In one patient, a chest x-ray revealed an old, healed tubercular lesion. The lesions disappeared completely in all patients within 3-6 months of either antituberculin therapy alone or antituberculin therapy combined with temporary pelvic colostomy. In the fifth patient, the lesion was removed, and a Thiersch skin graft was applied. Since these five cases occurred in a group of 75 cases of gastrointestinal tuberculosis, the authors conclude that anorectal tuberculosis may not be as uncommon as the literature indicates.

0454 INNERVATION OF THE APPENDIX IN HIRSCHSPRUNG'S DISEASE INVOLVING ALL OF THE COLON: A HISTOLOGICAL AND HISTOENZYMATIC STUDY. (Fre.) Nezelof, C.; Diebold, N. (Hopital des Enfants Malades, 149, rue de Sevres, F 75730 Paris Cedex 15, France). *Nouv. Presse Med.* 4(40):2859-2861; 1975.

The biopsy role of appendectomy in the total colonic type of Hirschsprung's disease is explained. The logic is based on the fact that autonomic innervation of the pediatric appendix reflects that of the cecum. There is little risk of perforation and littoral injury, which multiple colonic biopsies convey. A histochemical study was performed on 13 appendectomy samples taken during the first postnatal months, including 5 infants with total colon disease, 5 infants with various gastrointestinal disorders, and 3 infants with partial Hirschsprung involvement. Specimens were stained conventionally with hematoxylin-eosin and for nonspecific esterases, which demonstrated both efferent and afferent fibers equally well. Both cecal and appendix specimens were completely aganglionic in cases of total colonic involvement. The cecum and appendix were positive and the colon was entirely negative in cases of partial involvement. All intestinal samples were positive for autonomic neurons in the five patients with assorted gastrointestinal diseases. Appendectomy is recommended when an obstruction in the neonatal or postnatal period makes diagnosis and emergency treatment for the absence of colonic ganglia difficult.

LARGE INTESTINE

Ulcerative Colitis

09 PLASMA PREDNISOLONE LEVELS AFTER ADMINI-
STRATION OF PREDNISOLONE-21-PHOSPHATE AS A
TENTION ENEMA IN COLITIS. (Eng.) Powell-Tuck, J.;
nnard-Jones, J. E.; May, C. S.; Wilson, C. G.;
terson, J. W. (St. Mark's Hosp., London EC1, Eng-
nd). *Br. Med. J.* 1(1):193-195; 1976.

competitive protein binding assay was used to mea-
re plasma prednisolone levels in seven patients
th colitis after the administration of 20 mg
ednisolone-21-phosphate, p.o., or as a retention
ema. Prednisolone appeared in the plasma of all
tients after the enema, and concentrations rose to
peak within 3 hr. In two cases, the enema was
tained for only 0.6 and 1.6 hr, resp., and the peak
nded to occur earlier and the levels fell after
acuation. There was no obvious correlation with the
tivity of the disease or the distance traveled by
e enema in the other patients. The comparisons
tween the plasma prednisolone levels after p.o. and
ctal administration for the four patients who re-
ined the enema show that in two patients, the levels
re higher after p.o. administration, in one, the
vel was higher after the enema, and in one, the
vels were similar. These results suggest that the
ministration of prednisolone by retention enema may
ert a systemic, as well as local, effect.

10 PERICARDITIS ASSOCIATED WITH ULCERATIVE
COLITIS AND CROHN'S DISEASE. (Eng.)
dman, M. J.; Moir, D. J.; Holt, J. M.; Truelove,
C. (Dept. Medicine, Univ. Chicago, Chicago, IL).
J. Dig. Dis. 21(2):98-102; 1976.

cases (a 50-yr-old woman and a 31-yr-old man) of
flammatory bowel disease with cardiac complications
reported. The woman had had a rectovaginal
stula excised and subsequently developed symptoms
ggestive of Crohn's disease of the colon. She was
treated by a temporary relieving ileostomy with a separate distal stoma, through which infusions of hydrocortisone hemisuccinate solution were given. Almost 2 yr later the ileostomy was taken down and the continuity of the intestine restored. Seventeen days later, pericarditis was noted. Prednisolone (40 mg/day) brought about a remarkable improvement, with disappearance of the pericardial friction rub, clearing of the pleural effusion, and remittance of the chest pain. In the second patient, acute pericarditis appeared simultaneously with the initial presentation of ulcerative colitis. The patient responded to treatment with prednisolone (30 mg/day), azulfidine, and prednisolone-21-phosphate retention enemas. The findings in these two cases, taken in conjunction with four other cases reported in the literature, indicate that pericarditis, sometimes accompanied by a pleural effusion, must be considered as one of the systemic complications of inflammatory bowel disease.

PANCREAS

0520 CYSTADENOMA OF THE PANCREAS. TWO NEW CASES: ONE TREATED BY LEFT PANCREATECTOMY, THE OTHER BY DUODENOPANCREATECTOMY OF THE HEAD OF THE PANCREAS. (Fre.) Adloff, M.; Arnaud, J. P. (No affiliation given). *Chirurgie* 101(5):303-310; 1975.

The case histories of two patients with pancreatic cystadenoma are presented. A 51-yr-old woman, presenting with significant anemia, anorexia, vomiting, and epigastric sensitivity had been cholecystectomized 10 yr earlier; shortly thereafter, a pancreatic pseudocyst was discovered at laparotomy for hypochondrial discomfort. A pancreatic lesion due to splenic vein displacement was suspected on arteriography; a laparotomy was performed. A highly vascular intragastric mass contiguous to the tail of the pancreas was found. Gastrotomy confirmed that the posterior gastric wall was elevated by a tumor 8 cm in diameter. A caudal pancreatectomy with segmental gastric resection and a splenectomy were performed. A cystadenoma with multiple cystic cavities, which had been interpreted 10 yr earlier as a pseudocyst and managed by cystogastrostomy, was confirmed. A 46-yr-old woman with an unremarkable history presented with a mass in the right hypochondrium. A tumor occupying the head of the pancreas and compressing the stomach was found, and a duodenopancreatectomy was performed. Tumor histology showed multiple cysts separated by a plethora of calcified hyaline tissue.

PANCREAS

Pancreatitis

526 ANTIBIOTIC THERAPY IN ACUTE PANCREATITIS.
(Eng.) Cameron, J. L.; Howes, R.; Zuidema,
. D. (Johns Hopkins Medical Inst., Baltimore,
) 21205). *Surg. Clin. North Am.* 55(6):1319-1324;
975.

prospective randomized study was carried out in
5 patients to analyze the efficacy of prophylactic
ntibiotic therapy in acute pancreatitis. Forty-
ight patients received ampicillin (1 g, every 6
r), which was initially administered parenterally
nd later p.o. The antibiotic was given for 5 days
nless a septic complication developed. The other
7 patients were given no prophylactic antibiotics.
l patients received i.v. support, nasogastric
uction, pain medication, and i.m. atropine. In
ne patients receiving antibiotics, the pancrea-
itis was caused by ethanol ingestion in 45 and by
iliary disease in 2; among those not receiving
uch therapy, the corresponding figures were 41
nd 3, resp. There were no deaths in the series.
mong those receiving antibiotics, the average
ength of hospitalization was 9 days; in the other
roup, the average length was 12 days. This dif-
erence was not statistically significant. Serum
mylase values remained elevated for an average
f 2 days in both groups. Of the 95 patients,
1 developed septic complications. Of the five
atients who developed sepsis in the group treated
ith antibiotics, three developed pneumonia and
wo developed a pancreatic abscess. In two of
hese five patients, the organisms were resistant
ampicillin, and in the other three patients no
rganism could be cultured. Of the six patients
th complications in the group that received no
tibiotics, four had pneumonia, one had bacteremia,
d one had a pancreatic abscess. In five of these
x patients, the organism was ampicillin-sensitive.
here was one allergic reaction. Prophylactic anti-
otic therapy in acute pancreatitis does not prevent
scess formation and may make it more difficult
treat due to resistant organisms. It is recom-
ended that prophylactic antibiotic therapy should
t be used in acute pancreatitis.

LIVER AND BILIARY TRACT

0542 A CRITICAL EXAMINATION OF THE VALUE OF COMBINED DETERMINATIONS OF LECITHIN:CHOLESTEROL ACYLTRANSFERASE AND LIPOPROTEIN-X IN THE DIFFERENTIAL DIAGNOSIS OF LIVER DISEASE. (Eng.) Miller, J. P.; Johnson, K. (Dept. Medicine, Univ. Hosp. South Manchester, Withington Hosp., Manchester, M20 8LR, England). *Clin. Chim. Acta* 69(1):81-84; 1976.

The value of combined determinations of lecithin: cholesterol acyltransferase (LCAT) and lipoprotein-X (LPX) in the differential diagnosis of liver disease was investigated in 51 patients. Blood taken from the patients was divided into two portions. One was anticoagulated with EDTA (2 mg/ml) and the plasma was used for LCAT estimation; the other was allowed to clot and the serum was used for detection of LPX and measurement of serum cholesterol concentration. LPX was detected in the serum of 25 patients. The diagnosis of 21 patients (data not included on 4 patients) included 10 with extrahepatic obstruction (carcinoma of pancreas, 4; cholangiocarcinoma, 2; stone in common bile duct, 2; bile duct stricture, 1; pancreatitis, 1) and 11 with intrahepatic cholestasis (chronic active hepatitis, 4; other cirrhosis, 3; viral hepatitis, 3; halothane hepatitis, 1). Plasma LCAT estimation in these LPX-positive patients was not useful in differentiating between those who had intrahepatic cholestasis and those who had extrahepatic biliary obstruction. Plasma from normal subjects assayed against a standard substrate gave esterification rates in excess of 20 nmol/ml/hr. It is concluded that the range of plasma LCAT activity is similar in patients with intrahepatic cholestasis and extrahepatic obstruction and does not enable distinction to be made between them.

0543 THE ROLE OF HEREDITY IN CERTAIN CHRONIC LIVER DISEASES IN THE ADULT. (Fre.) Bourel, M.; Simon, M.; Le Marec, B.; Brissot, P.; Alexandre, J. L. (Bloc Hopital Villejean-Pontchaillou, 35011 Rennes, France). *Bordeaux Med.* 8(7):743-757; 1975.

A review of various genetically transmitted adult liver diseases is presented. Wilson's disease, a copper storage disease, is an autosomal recessive defect characterized by hepatolenticular degeneration and elevated transaminases. Transmission of hemochromatosis remains controversial; the literature supports evidence for both autosomal dominant and recessive transmission. There are difficulties with both views, so that the argument for autosomal dominance must also admit variable penetrance, and the argument for autosomal recessive must admit intermediate heredity. Among the constitutional hyperbilirubinemias, the nonconjugated Crigler-Najjar form is thought to be autosomal recessive, and the Gilbert type is thought to be autosomal dominant with variable penetrance. The conjugated form was construed as autosomal dominant up to 1970 when additional evidence supported it as autosomal recessive, which is now the dominant view. Among the sphingolipidoses, Landing's disease, Gaucher's disease, and Niemann-Pick's disease are indisputably autosomal recessive.

0544 NOTES ON HISTOENZYMOLOGY IN HEPATOLOGY (EXCLUSIVE OF CANCER). (Fre.) Traissac, F. J.; Paccalin, J.; Alberti, E. M. (No affiliation given). *Bordeaux Med.* 8(10):1199-1210; 1975.

A review of histochemical methods is presented, and the role of enzyme histochemistry in the diagnosis of glycogenoses, hepatitis, obstructive cholestases, cirrhoses, and intoxication is examined. Of the six types of glycogenoses, four involve the liver, and two are accessible to histochemical assay: von Gierke's and Hers' diseases. In viral hepatitis, alkaline phosphatase is elevated; ATP is reduced in the ducts and increased in the Kupffer cells, sinusoids, and periportal spaces; and 5-nucleotidase is decreased in the ducts. The enzymes more specific to hepatic cells, such as transaminases, are usually reduced, but there is no histoenzymological profile specific to hepatitis. In acute hepatitis, the enzymatic pattern is just as variable, but more marked. Only acid and alkaline phosphatases are found in necrotic areas. The variations in cholestatic hepatitis resemble those for the acute form, except that the levels of glucose-6-phosphatase and the pentose pathway enzymes are lower. Obstructive cholestases present the same type of picture, with most of the enzymes diminished, except for alkaline phosphatase. The lysosomal enzymes are elevated in active cirrhosis. In primary cirrhosis, the pattern varies according to case; in general, either a pattern similar to extrahepatic cholestasis, with retention of certain activities, or one resembling intrahepatic cholestasis is found. Patients with the extrahepatic form tend to have longer survivals.

0545 HAEMOLYSIS IN LIVER DISEASE: RELATIONSHIP TO ERYTHROCYTE MEMBRANE FUNCTION, SERUM BILIRUBIN CONCENTRATION AND PLASMA ELECTROLYTE DISTURBANCES. (Eng.) Powell, L. W.; Halliday, J. W.; Cooksley, W. G. E. (Royal Brisbane Hosp., Brisbane, Queensland 4029, Australia). *Aust. N.Z. J. Med.* 6(1):3-6; 1976.

A study was made to determine whether the hemolysis observed in patients with liver disease is related to dysfunction of the RBC membrane resulting from abnormalities in plasma electrolyte, urea, or bilirubin concentrations. The study group was composed of 45 patients, of whom 4 had acute viral hepatitis; 4, acute alcoholic hepatitis; 24, hepatic cirrhosis; 5, jaundice due to extrahepatic obstruction; 2, acute intravascular hemolysis associated with liver disease; and 6, miscellaneous diseases associated with plasma electrolyte disturbances. RBC membrane permeability was measured by the rate of ^{22}Na influx. In the six patients with abnormalities in plasma electrolyte concentrations, the Na influx was significantly increased. In these patients the abnormal membrane permeability probably reflected a more generalized cell membrane abnormality. However, plasma electrolyte concentration and RBC membrane permeability were normal in the majority of patients with liver disease, all of whom had a reduced RBC survival, and neither electrolyte concentration nor RBC membrane permeability correlated significantly with the half-life (T_{50}) for ^{51}Cr-labeled RBC. Only three patients with liver disease showed a marked increase in ^{22}Na influx. They did not all have severe hemolysis, but spherocytosis was present in each. It is concluded that the Na^+ leak in the RBC of patients with hereditary spherocytosis is not related etiologically to hemolysis. This study does not support a pathogenic role of increased membrane permeability in the premature destruction of RBC in liver disease. The correlation between the T_{50} for ^{51}Cr-RBC and serum bilirubin levels indicates that hemolysis in patients with liver disease is related to the severity of the hepatic disorder, rather than to a direct effect of bilirubin on RBC.

0546 DIFFICULTIES IN THE ETIOLOGICAL DIAGNOSIS OF CHOLESTASES. (Fre.) Traissac, F. J.; Borg, R.; Blanc, A.; Ragnaud, J. M.; Weber, F. (No affiliation given). *Bordeaux Med.* 8(9):1067-1084; 1975.

A compendium summarizes various aspects of cholestasis for differential diagnostic purposes. The physiopathology, clinical picture, biology, scintigraphy, laparoscopy, tomoechography, radiology, and pathological anatomy are topically reviewed. The preclinical values are most often inadequate in defining the cause or even the level of involvement. Scintigraphy cannot be used. Peritoneoscopy provides valuable data, but is not always diagnostic. Among the current radiological procedures, only gastroduodenal transit, which reveals indirect signs of tumor, plays a role. Retrograde catheterization of the ductal system under duodenoscopic control is used for opacification of the common duct or duct of Wirsung. Retroperitoneal transparietohepatic cholangiography is the method of choice, since exploratory laparotomy must be avoided, for differentiating intra- and extrahepatic localization.

0547 HEPATIC INFARCTION: A CLINICOPATHOLOGIC STUDY OF SEVEN CASES. (Eng.) Chen, V.; Hamilton, J.; Qizilbash, A. (Henderson General Hosp., 711 Concession St., Hamilton, Ontario, Canada L8V 1C3). *Arch. Pathol. Lab. Med.* 100(1):32-36; 1976.

The clinical, laboratory, autopsy, and microscopic findings from seven cases of hepatic infarction are presented, and the causes are also reviewed. Hepatic infarction was defined as ischemic necrosis affecting more than one hepatic lobule. All patients had epigastric or right upper quadrant pain, and jaundice and fever were present in six cases. The liver was palpable in only three patients (weight of liver found between 1,350 g and 2,800 g at autopsy). Two patients had infarcts that were of less than 24-hr duration. The sinusoids were filled with blood, corresponding to the hemorrhagic appearance seen grossly. The infarcts consisted of parenchymal coagulative necrosis with partial sparing of the portal tracts and central veins. The liver cells appeared necrotic. In two cases, the infarcts were 24-48 hr old. In these, the central zones showed necrosis of all structures, including portal tracts and central veins. The sinusoids appeared empty. Surrounding the necrotic zone was a variable area of partial necrosis showing congestion. In this area, viable liver cells surrounded the portal tracts. A similar narrow zone of surviving liver cells was also seen in the subcapsular area. In two cases, the infarcts were between 48 and 72 hr old and three definite zones were identified. The central necrotic zone was surrounded by a zone of inflammatory reaction. Outside the inflammatory zone was a variable zone of partial necrosis in which intact portal tracts were surrounded by a narrow rim of viable liver cells. In one case, the infarcts were about 2 weeks old. These involved the regenerative nodules of macronodular cirrhosis. The cirrhosis was complicated by the development of hepatocellular carcinoma with extensive portal vein thrombosis. The size of the infarcts varied from those that involved the entire lobe to one that was approximately 0.5 cm in size. Mild fatty change occurred in the surviving liver cells of four patients, and cholestasis occurred in four patients. The causes of infarction included: ligation of the right hepatic artery; thrombosis of the hepatic, celiac, splenic, and superior mesenteric veins; thrombosis of the hepatic, celiac, splenic, and superior mesenteric arteries and thrombosis of the portal vein; and thrombosis of the main portal vein and intrahepatic branches. Hepatic infarction may not be as uncommon as has been previously suggested.

0548 SELECTION OF DISCRIMINATORY BIOCHEMICAL VARIABLES FOR THE DIAGNOSIS OF INTRAHEPATIC CHOLESTASIS, EXTRAHEPATIC CHOLESTASIS AND LIVER CANCER. (Fre.) Plomteux, G.; Toulet, J. (Service de Chimie Medicale, 1, rue des Bonnes-Villes, 4000 Liege, Belgium). *Arch. Fr. Mal. App. Dig.* 64(4): 317-324; 1975.

A method for selecting a manageable subset of variables is proposed that would preserve the same amount of information as the conventional 30 variables routine for liver diagnosis. The clinical samples included 15 icteric patients with primary or secondary liver carcinoma, but without extrahepatic obstruction, 33 icteric patients with extrahepatic obstruction, and 49 icteric cases with intrahepatic cholestasis. The controls consisted of 100 patients without hepatobiliary involvement. Determination was made on the basis of a preferred subset obtained from the combination of four tests with six variables, whose discriminatory function was compatible with the criteria of variance and covariance. The 10 factors included alkaline phosphatase, 5-nucleotidase, thymol, GPT, and glutamic dehydrogenase, all of which discriminate intrahepatic cholestasis from extrahepatic obstruction and tumor, and esterases-A, total LDH, iso-LDH-4, ornithine carbamoyl-transferase, and isocitric dehydrogenase, all of which, along with glutamic dehydrogenase, differentiate extrahepatic cholestasis from tumors. These 10 variables were 93% diagnostic of the cited clinical groups.

0549 STATUS REPORT ON PROPHYLAXIS OF WILSON'S DISEASE. (Fre.) Sternlieb, I. (Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, NY 10461). *Bull. Acad. Natl. Med. (Paris)* 159(6): 479-483; 1975.

Diagnostic aspects of Wilson's disease are reviewed. The disease is presently understood to be the result of both chronic copper intoxication and a deficiency in ceruloplasmin (CP) synthesis. Diagnosis is biochemically possible, and the specific therapy is D-penicillamine. Genetically, it was formerly assumed to have homozygous expression only. This view is currently not so diagnostically unequivocal, since at least 10% of the heterozygotes bear homozygous traits, and 5% of the homozygotes carry homozygous traits. Light microscopy of liver punch biopsies helps to confirm the biochemical values, but ultrastructural findings of mitochondrial lesions, where steatosis is microscopically frank, is pathognomic. In a study of 80 apparently healthy subjects who were biochemically borderline, 76 were given D-penicillamine (1 g/day x 365, minimum). Of the 76, 60 had reduced CP and elevated hepatic copper; 3 had normal CP, elevated transaminases, and increased hepatic copper; 8 had diminished CP and other biochemical anomalies; and 5, otherwise identical to the first group, had Kayser-Fleischer rings without clinical evidence of disease. Complications occurred in three cases: nephrosis, nephrocalcinosis, and perforating elastosis. In no case was there physical or intellectual retardation.

0550 CHENODEOXYCHOLIC ACID INHIBITS INCREASED CHOLESTEROL AND CHOLESTANOL SYNTHESIS IN PATIENTS WITH CEREBROTENDINOUS XANTHOMATOSIS. (Eng.) Salen, G.; Meriwether, T. W.; Nicolau, G. (Veterans Hosp., East Orange, NJ 07019). *Biochem. Med.* 14(1): 57-74; 1975.

The effects of chenodeoxycholic acid (CDCA) on cholesterol and cholestanol biosynthesis were evaluated in two subjects with cerebrotendinous xanthomatosis (CTX) by isotope kinetic techniques and in one subject by hepatic enzyme analysis. Sterol-specific-activity decay curves conformed to two-pool models, after i.v. pulse labeling with [4-^{14}C]cholesterol and [1,2-^{3}H]cholestanol, before and during treatment with CDCA (0.75 g/day). Calculations of daily production rates and of the size of the rapidly exchangeable kinetic pools of cholesterol and cholestanol were compared during both periods. Since diets contained no cholestanol and were low in cholesterol (<45 mg/day), production rates approximated daily synthesis. During CDCA treatment, average plasma cholestanol decreased 45%, and plasma cholesterol rose 23%. Average cholestanol synthesis decreased from 53 to 14 mg/day, and average cholesterol synthesis was reduced from 1,036 to 434 mg/day. In one CTX subject, the hepatic activity of 3-hydroxy-3-methylglutaryl coenzyme A reductase declined 54% after 7 days of bile acid treatment. These data indicate that CDCA suppressed elevated cholesterol and cholestanol synthesis in CTX, and suggest that this primary bile acid may be useful in preventing the clinical progression of the disease.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

0639 CHOLESTATIC HEPATITIS WITH A CHRONIC COURSE. SEVEN CASES. (Fre.) Frexinos, J.; Rumeau, J. L.; Pascal, J. P.; Tournut, R.; Suduca, P.; Ribet, A. (Hopital de Purpan, F 31052 Toulouse Cedex, France). *Nouv. Presse Med.* 5(1):19-22; 1976.

The clinical picture, paraclinical data, hepatobiliary histology, and therapeutic modalities in seven patients with chronic cholestatic hepatitis are generalized. The duration of disease was between 18 and more than 36 months. There was no extrahepatic obstruction. Paraclinically, the bilirubin exceeded 100 mg/l, the serum lipids were equal to or greater than 15 g/l, the cholesterolemia was 4 g/l or higher, and the alkaline phosphatase was 500 IU/l or higher. There was a female predominance (6/7). The Australia antigen and the smooth muscle and mitochondrial antibodies were absent. There was a marked reduction in the number of "permeable" bile ducts at the level of the portal spaces. The course of the disease was relatively little influenced by a variety of treatments. Cholestyramine was administered in three cases with completely misleading results. Duodenal intubation was successful for 2 months in six cases. Doses of 60-80 mg/day methyl prednisolone were continued for 2 months, followed by 20 mg/day prednisolone and 50 mg/day azathioprine for more than 1 yr. After an interval of 18-24 months, four patients had completely normal liver function, with no sign of persistent necrosis. In the remaining three cases, a cholestatic syndrome persisted 28-36 months, with transaminase elevations between 100 and 200 IU/l.

Acute Viral Hepatitis

0643 FULMINATING HEPATITIS TREATED BY PLASMAPHERESIS. (Fre.) Boland, J.; Broux, R.; Bury, J.; Pirotte, J. (Institut de Medecine, Hopital de Baviere, Boulevard de la Constitution 66, B-4000 Liege, Belgium). *Acta Gastroenterol. Belg.* 38(5/6):207-217; 1975.

The case history of a fulminating serum hepatitis managed by plasmapheresis is presented. A 24-yr-old woman with an unexceptional medical history presented with asthenia, arthralgia, constipation, vomiting, subicterus, and hepatomegaly. The icterus was progressive and the patient became increasingly torpid and finally comatose, with alternating hypo- and hypertonicity. The cholestasis was confirmed para-clinically. Initial treatment included high-dose corticosteroids and neomycin (1 g x 3). The patient was found to be serologically positive for Australia antigen. An initial plasmapheresis of 10,500 liters elicited a regression of coma and icterus. A second plasmapheresis restored consciousness, and the patient was released in 2 weeks with only moderately elevated transaminases.

Chronic Hepatitis

)677 CLINICAL EXTRAHEPATIC MANIFESTATIONS OF
CHRONIC HEPATITIS AND OF PRIMARY BILIARY
:IRRHOSIS. (Fre.) Buffet, C.; Etienne, J. P.
Service d'Hepatologie et de Gastro-Enterologie,
lopital Antoine-Beclere, F 92140 Clamart, France).
rch. Fr. Mal. App. Dig. 64(6):539-547; 1975.

. survey of the past decade's literature on the
requency, clinical picture, and physiopathology
f extrahepatic signs in chronic hepatitis andd
rimary biliary cirrhosis is presented. In chronic
epatitis, 17% of the cases demonstrated rheumatoid
igns and 80% of these were arthralgia and arthritis;
2% showed renal signs, especially tubular acidosis
nd chronic glomerulonephritis; 6.2% had colonic
ymptoms (ulcerative colitis); 20% had Sjogren's
yndrome; 10% had thyroid disorders (Hashimoto's
hyroid, hyperthyroidism, simple goiter); 17% had
ıtaneous symptoms, especially melanoderma; and
9% had pleuropulmonary symptoms, especially pleurisy
ıd alveolar lung fibrosis. In primary cirrhosis,
ıe distribution is 4% rheumatoid, 2% renal, 2%
olonic, 3.6% scleroderma, 3% Sjogren's syndrome,
% thyroid, and 2% pleuropulmonary. No correlations
ppear possible.

LIVER AND BILIARY TRACT

Cirrhosis

0697 187 PORTACAVAL ANASTOMOSES. A STATISTICAL ANALYSIS OF PROGNOSTIC FACTORS. II. COMPARATIVE STUDY OF THE RESULT OF ANASTOMOSIS WITH OR WITHOUT INTERRUPTION OF THE PORTAL VEIN. DISCUSSION. (Fre.) Leger, L.; Lenriot, J. P.; Duclos, J. P.; Lemaigre, G. (Hopital Cochin, 16, rue de Teheran, 75-Paris, France). *J. Chir. (Paris)* 109(4):429-450; 1975.

A comparative statistical study of survival rates after anastomosis with and without portal vein interruption is presented. The clinical sample included 119 end-to-side anastomoses and 4 end-to-end portorenal anastomoses. The postoperative mortality was 26 of 123, due primarily to hepatic insufficiency. Of 94 patients surviving 2 postoperative months, 58 died within 6 months to 12 yr (average, 3.75 yr) and 36 are still living. Among the 58, progressive or sudden hepatic deficit was responsible for death in 39 cases. Patient age was the most important factor determining short-term survival. Sex and the permeability or thrombosis of the shunt were significant in determining longer term survival. At 1 yr, 35% of the men and 14% of the women had succumbed. Those with permeable shunts had a 1-yr mortality of 27%, and those wit thrombosed shunts, a 47% mortality. Of 80 1-yr survivors, the result was satisfactory in 48, moderately successful in 11, and poor in 21; 15% experienced thrombosis at the anastomosis. Portal continuity was preserved in 64 patients, including 48 with portacaval side-to-side anastomoses, 14 with end-to-side anastomoses, and 2 with side-to-end anastomoses. In this group, the postoperative mortality was 19 in 2 months, mainly from hepatic deficit. The biological status of the host was the primary factor in immediate postoperative survival. Survival patterns showed that 45 patients lived 2 months or more, including 14 who lived up to 5 yr; 29 died, primarily from hepatic insufficiency. The surgical result was satisfactory in 16 cases, moderately successful in 11, and poor in 9. The anastomotic thrombosis rate was 19-35%. Survival favors conservation of the portal trunk and end-to-side anastomosis.

0698 CLINICAL TYPES AND DRUG THERAPY OF RENAL IMPAIRMENT IN CIRRHOSIS. (Eng.) Rodes, J.; Bosch, J.; Arroyo, V. (Hospital Clinico y Provincial, Univ. Barcelona, Barcelona, Spain). *Postgrad. Med. J.* 51(598):492-497; 1975.

The clinical course and prognosis in 31 cirrhotic patients with functional renal failure (FRF) were compared with those in 34 cirrhotic control patients with ascites and normal creatinine clearance. The differential diagnosis of FRF and other types of renal dysfunction occurring in cirrhotic patients is discussed with reference to 17 FRF patients, 5 patients with acute tubular necrosis, and 9 patients with chronic renal disease. The therapeutic approach in seven additional FRF patients is described. In ll of the 31 cirrhotic FRF patients, renal failure followed a rapidly progressive course after hospitalization with a progressive increase in plasma urea concentration, low urinary sodium concentration, nd a marked fall in urine volume. All 11 had a complication (hemorrhage, infection) or had undergone a procedure (cholecystectomy) that could have predisposed to FRF. A second group of 11 patients (group 2) was admitted with ascites and renal failure, for which no reason could be found. Most lost their ascites with diuretic therapy. In the last nine atients, the initial evolution was identical to that of group 2 until some complication or operation occurred that hastened the course of the renal failure. wenty-three of the 31 patients died, while only 3 of the 34 cirrhotic controls died. When the eight surviving FRF patients in group 2 were followed up after 11 months, over 50% ad died. This death rate was not reached in the ontrols until 24 months of follow-up. Seven FRF atients were treated with plasma volume expanders human plasma or serum albumin). Furosemide (200 mg, -hourly) was administered i.v. The dosage was doubled f diuresis had not ensued or if there was a rise in entral venous pressure, but it was gradually tapered ccording to the diuretic response. Preliminary esults of treatment of FRF with plasma volume xpansion in combination with high doses of furo- emide demonstrate a long-term improvement in renal unction.

Gallbladder and Biliary Tract Diseases

0723 SPECTRUM OF CHOLANGITIS. (Eng.) Saik, R. P.; Greenburg, A. G.; Farris, J. M.; Peskin, G. W. (Veterans Admin. Hosp., 3350 La Jolla Village Drive, San Diego, CA 92161). *Am. J. Surg.* 130(2): 143-150; 1975.

Experience with 36 cases of acute cholangitis from among 402 patients with biliary disease seen in a 3-yr period is presented. The symptoms included spiking fever (94.4%) or chills (77.7%); elevated bilirubin (91.6%), alkaline phosphatase (88.8%), and and white blood cell count (97.2%); history and ce evidence of bile duct obstruction or manipulation; ence and evidence of sepsis. Pain was present in all cases. Thirty patients had biliary calculus, and four had associated pancreatitis. Cholangitis developed in five patients after radiological procedures. Bile cultures for organisms were found in 93% of the patients, and more than 50% of these had growth of more than one organism. Of the 28 patients who underwent surgery, only 5 did not have exploration of the common bile duct, and 4 of these died. Surgical procedures included cholecystectomy (20 patients), cholecystotomy (4), common bile duct exploration (23), operative cholangiography (23), sphincteroplasty and choledochoduodenostomy (3 each), and cholecystoduodenostomy (1). There were three other operative deaths; two were from hemorrhage, and the third occurred at home in a patient with adenocarcinoma of the gallbladder and common duct stones. All patients who died underwent a period of shock. Early diagnosis and confirmation, early administration of antibiotics, correction of shock, low cardiac output, and evaluation of possible clotting abnormalities are essential in the management of acute cholangitis in elderly patients. Operative intervention including duct drainage was recommended in all cases, except those with immediate response to antibiotics, along with operative bile and peritoneal culture and satisfactory operative cholangiogram. Postoperative monitoring of vital signs and careful preparation after ductal manipulation are also stressed.

0769 A DOUBLE BLIND CROSSOVER COMPARISON OF LOPERAMIDE WITH DIPHENOXYLATE IN THE SYMPTOMATIC TREATMENT OF CHRONIC DIARRHEA. (Eng.) Pelemans, W.; Vantrappen, G. (Gastrointestinal Unit, Dept. Medicine, Akademisch Ziekenhuis Sint-Rafael, Leuven, Belgium). *Gastroenterology* 70(6):1030-1034; 1976.

The symptomatic antidiarrheal efficacies of loperamide and diphenoxylate were compared in a double-blind crossover study using a flexible dosage schedule in 23 patients with chronic diarrhea of diverse origin (irritable colon syndrome, Crohn's disease, Crohn's disease with surgery, Gardner's syndrome with subtotal colectomy, or ulcerative colitis with total colectomy and ileostomy). At the start of each of two treatment periods (median 26 and 24 days), each patient was supplied with a bottle of 150 capsules, each containing either 2 mg of loperamide or 5 mg of diphenoxylate plus 0.05 mg of atropine sulfate. Patients were instructed to adjust the dose according to the antidiarrheal effect required, but not to exceed five capsules a day. In the 17 patients who were evaluated by means of stool frequency and consistency, both loperamide and diphenoxylate effected significant improvement. Treatment with loperamide was significantly ($p=0.01$) better than treatment with diphenoxylate. The median daily stool weight in six patients with colectomy and ileostomy significantly decreased with loperamide ($p=0.03$), but not with diphenoxylate ($p=0.12$). Twenty patients expressed a treatment preference, with loperamide being favored more frequently (17 patients) than diphenoxylate (3 patients, $p=0.002$). The average daily dose of loperamide (6.9 mg) was 2.5 times lower than that of diphenoxylate (17.7 mg, $p<0.001$). Loperamide was well tolerated and produced few adverse reactions (occasional constipation in 3 patients, fatigue in 1 patient, and epigastric pain in 1 patient). The results show that loperamide is an effective p.o. antidiarrheal agent capable of controlling or significantly reducing chronic diarrhea.

0797 REAPPRAISAL OF SKIN FLAP CLOSURE FOR NEONATAL GASTROSCHISIS. (Eng.) Thompson, J.; Fonkalsrud, E. W. (Univ. California Sch. Medicine, Los Angeles, CA 90024). *Arch. Surg.* 111(6):684-687; 1976.

0798 RETROSTERNAL GOITRE PRESENTING AS BLEEDING OESOPHAGEAL VARICES [Abstract]. (Eng.) Barber, P. V.; Edwards, J. D.; Enoch, B. A.; Shafiq, M.; Vallon, A. G. (North Manchester General Hosp., Crumpsall, M8 6RB, England). *Br. Med. J.* 1(6009):594; 1976.

0799 MASSIVE INTESTINAL HAEMORRHAGES. (Eng.) Karady, G.; Vegh, G.; Bock, G. (Semmelweis Medical Univ. I, Surgical Clinic, Budapest, Hungary). *Am. J. Proctol.* 27(2):33-40, 42; 1976.

0800 UPPER GASTROINTESTINAL HAEMORRHAGE—A REVIEW OF 100 CASES. (Eng.) Lanigan, M. W. (Hosp. Sick Children, Toronto, Ontario, Canada). *Med. J. Aust.* 63(1):253-256; 1976.

0801 SEQUENTIAL GASTROSCOPY AND QUANTITATION OF GASTROINTESTINAL BLOOD LOSS USING RADIOACTIVE FECAL MARKERS: EFFECT OF ASPIRIN, FENOPROFEN AND ACETAMINOPHEN IN RHEUMATOID ARTHRITIS [Abstract]. (Eng.) Loebl, D. M.; Craig, R. M.; Culic, D.; Ridolfo, A. S.; Falk, G. (Dept.

Medicine, Northwestern Univ., Chicago, IL). *Clin. Res.* 23(4):519A; 1975.

0802 INTESTINAL PHOSPHATE TRANSPORT IN FAMILIAL HYPOPHOSPHATEMIC RICKETS. (Eng.) Glorieux, F. H.; Morin, C. L.; Travers, R.; Delvin, E. E.; Poirier, R. (Montreal Shriners Hosp., Montreal, Quebec, Canada). *Pediatr. Res.* 10(7): 691-696; 1976.

0803 TRIMETHOPRIM-SULFAMETHOXAZOLE THERAPY FOR SHIGELLOSIS. (Eng.) Nelson, J. D.; Kusmiesz, H.; Jackson, L. H.; Woodman, E. (Southwestern Medical Sch., 5323 Harry Hines Blvd., Dallas, TX 75235). *JAMA* 235(12):1239-1243; 1976.

0804 SCREENING FOR STAPHYLOCOCCAL ENTEROTOXINS IN FOOD. (Eng.) Tatini, S. R.; Cords, B. R.; Gramoli, J. (Dept. Food Science, Nutrition, Univ. Minnesota, St. Paul, MN 55108). *Food Technol.* 30(4):64, 66, 70, 72-74; 1976.

0805 TYPING OF THE VIBRIOS BY SPECIFIC O-SERA. (Rus.) Krasnova, I. N.; Trager, R. S.; Vedmina, E. A.; Ogneva, N. S.; Ibragimov, F. K.; Sobolev, V. R. (Inst. of Human Morphology, USSR Acad. of Medical Sciences, Moscow, USSR). *Z. Mikrobiol. Epidemiol. Immunobiol.* (2):37-41; 1975.

0806 STUDIES ON PHYSIOLOGICAL AND CLINICO-PATHOLOGICAL INTERRELATIONS OF GASTRO-ENTERO-PANCREATIC HORMONES [Abstract]. (Eng.) Wada, T.; Ohara, H.; Yachi, A.; Takasu, S.; Yamada, S.; Kihara, A.; *et al.* (Sapporo Medical Coll., Sapporo, Japan). *Jpn. J. Med.* 14(2):122; 1975.

0807 ABDOMINAL EMERGENCIES IN INFANTS. (Eng.) Altman, R. P.; Randolph, J. G.; Breckbill, D. L.; McSweeney, W. J. (Children's Hosp. Natl. Medical Center, Washington, DC). *Adv. Surg.* 9:305-364; 1975.

0808 HISTOLOGIC STUDY ON A DELAYING FACTOR IN THE HEALING OF AN ANASTOMOTIC WOUND. (Eng.) Nakamura, N.; Yoshida, K.; Taguchi, Y. (Jikei Univ. Sch. Medicine, 3-25-8-Nishi Shinfashi Minato-ku, Tokyo 105, Japan). *Chir. Gastroenterol.* 9(3):355-361; 1975.

0809 THE USE OF CONTROLLED CLINICAL TRIALS IN GASTRIC SURGERY. (Eng.) Kennedy, T. (Royal Victoria Hosp., Grosvenor Road, Belfast, BT12 6BA Northern Ireland). *Acta Chir. Belg.* 75(1): 122-128; 1976.

0810 DRUGS DERIVED FROM CANNABINOIDS. 5. $\Delta^{6a,10a}$-TETRAHYDROCANNABINOL AND HETEROCYCLIC ANALOGS CONTAINING AROMATIC SIDE CHAINS. (Eng.) Winn, M.; Arendsen, D.; Dodge, P.; Dren, A.; Dunnigan, D.; Hallas, R.; Hwang, K.; *et al.* (Div. Medicinal Chemistry and Pharmacology, Abbott Lab., North Chicago, IL 60064). *J. Med. Chem.* 19(4):461-471; 1976.

0811 HOST DEFENSE MECHANISMS IN THE GASTRO-INTESTINAL TRACT. (Eng.) Walker, W. A. (Massachusetts General Hosp., Boston, MA 02114). *Pediatrics* 57(6):901-916; 1976.

0812 DUODENAL BILE ACID CONCENTRATION AND COMPOSITION DURING TREATMENT WITH A BILE SEQUESTERING AGENT [Abstract]. (Eng.) Ritland, S.; Fausa, O. (Rikshospitalet, Univ. Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(34):29-30; 1975.

0813 INTESTINAL COLONIZATION WITH Lactobacilli STRAINS IN NEUTROPENIC PATIENTS. (Eng.) Hensgens, C.; Klastersky, J. (Institut Jules Bordet Rue Heger-Bordet, 1, 1000 Bruxelles, Belgium). *Biomedicine* 25(1):11-15; 1976.

0814 GASTROINTESTINAL SOMATOSTATIN CELLS IN THE HUMAN FETUS. (Eng.) Dubois, P. M.; Paulin, C.; Dubois, M. P. (Lab. d'Histologie et Embryologie U.E.R. Medicale Lyon Sud-Ouest, B.P. no. 12-69600 Oullins, France). *Cell Tissue Res.* 166(2):179-184; 1976.

0815 CONDITIONS AFFECTING THE BIOSYNTHESIS OF LIPIDS IN THE SMALL INTESTINE. (Eng. Mansbach, C. M., II (Veterans Admin. Hosp., 508 Fulton St., Durham, NC 27705). *Am. J. Clin. Nutr.* 29(3):295-301; 1976.

0816 THE EFFECT OF MATERNAL UNDERNUTRITION ON THE OXYGEN CONSUMPTION AND LIVER ENZYME ACTIVITY OF ADULT PROGENY. (Eng.) Yang, G.-Y. (Natl. Defense Medical Center, Taipei, Taiwan). *Chin. Med. J.* 22(2):83-89; 1975.

0817 SOCIAL FACTORS IN THE EPIDEMIOLOGY OF INTESTINAL INFECTIONS. (Rus.) Nikitin D. P. (Central Inst. Hygiene Information, USSR). *Zh. Mikrobiol. Epidemiol. Immunobiol.* (2):3-6; 1975.

0818 GASTRIC ACID SECRETION AND ACUTE GASTRO DUODENAL DISEASE AFTER BURNS. (Eng.) Czaja, A. J.; McAlhany, J. C.; Pruitt, B. A., Jr. (US Army Inst. Surgical Res., Brooke Army Medical Center, Fort Sam Houston, TX 78234). *Arch. Surg.* 111(3):243-245; 1976.

0819 A CLINICAL STUDY ON REGULATION OF MOTILITY OF DIGESTIVE TRACT BY GASTROINTESTINAL HORMONES. (Eng.) Ishikawa, M.; Ishimori, A. (Yamagata Univ. Sch. Medicine, Yamagata, Japan). *J. Med.* 14(1):21-25; 1975.

Parasitology

0820 TROPICAL DISEASES OF THE LIVER AND BILE DUCTS. (Eng.) Reeder, M. M. (Walter Reed Army Medical Center, Washington, DC 20012). *Semin. Roentgenol.* 10(3):229-243; 1975.

0821 ANALYSIS OF SYMPTOMS AND SIGNS RELATED WITH INTESTINAL PARASITOSIS IN 5,215 CASES. (Eng.) Biagi, F.; Lopez, R.; Viso, J. (Departamento de Parasitologia, Universidad Nacional Autonoma de Mexico, Mexico). *Prog. Drug Res.* 19:10-22; 1975.

0822 TREATMENT OF INTESTINAL PARASITES IN AUSTRALIAN ABORIGINAL CHILDREN. (Eng.) Best, J. C.; Welch, J. S.; Filippich, C.; McPhee, L. (Librarian, Queensland Inst. Medical Res., Herston Road, Valley, Brisbane, Queensland, Australia 4006). *Med. J. Aust.* 63(1/2):14-20; 1976.

0823 MULTIPLE COLONIC STRICTURE FORMATION AND AMOEBIASIS. A CASE REPORT. (Eng.) Smith, M. A. P. (Groote Schuur Hosp., Cape Town, South Africa). *S. Afr. Med. J.* 50(15):592-594; 1976.

0824 TINIDAZOLE IN TREATMENT OF ACUTE AMOEBIC DYSENTERY IN CHILDREN. (Eng.) Scragg, J. N.; Rubidge, C. J.; Proctor, E. M. (Dept. Paediatrics, Child Health, Univ. Natal, P.O. Box 17039, Congella, 4013, Natal, South Africa). *Arch. Dis. Child.* 51(5):385-387; 1976.

0825 THE "NEW DISEASE" STATUS OF HUMAN ANISAKIASIS AND NORTH AMERICAN CASES: A REVIEW. (Eng.) Jackson, G. J. (Div. Microbiology, Food Drug Admin., Washington, DC 20204). *J. Milk Food Technol.* 38(12):769-773; 1975.

0826 EFFECT OF HOOKWORM DISEASE ON THE STRUCTURE AND FUNCTION OF SMALL BOWEL. (Eng.) Chuttani, H. K.; Misra, R. C. (Maulana Azad Medical Coll., New Delhi, India). *Prog. Drug Res.* 19:44-47; 1975.

0827 HOOKWORM ANAEMIA AND INTESTINAL MALABSORPTION ASSOCIATED WITH HOOKWORM INFESTATION. (Eng.) Saraya, A. K.; Tandon, B. N. (All India Inst. Medical Sciences, New Delhi 110016, India). *Prog. Drug Res.* 19:108-118; 1975.

0828 EPIDEMIOLOGY AND PUBLIC HEALTH IMPORTANCE OF INTESTINAL NEMATODE INFECTIONS IN LATIN AMERICA. (Eng.) Botero R, D. (Sch. Medicine, Univ. Antioquia, Medellin, Columbia). *Prog. Drug Res.* 19:28-43; 1975.

0829 IMMUNODIAGNOSIS OF HELMINTHIC INFECTIONS. (Eng.) Sawada, T.; Sato, K.; Takei, K. (Sch. Medicine, Gunma Univ., Maebashi, Japan). *Prog. Drug Res.* 19:119-127; 1975.

0830 CHEMOTHERAPY OF INTESTINAL HELMINTHIASIS. (Eng.) Standen, O. D. (Wellcome Res. Lab., Langley Court, Beckenham, Kent, England). *Prog. Drug Res.* 19:158-165; 1975.

0831 COMPARATIVE EFFICACY OF NEWER ANTHELMINTICS. (Eng.) Vakil, B. J.; Dalal, N. J. (J. J. Group Hosps., Bombay 8, India). *Prog. Drug Res.* 19:166-177; 1975.

0832 MECHANISMS OF ANTHELMINTIC ACTION. (Eng.) Sheth, U. K. (K.E.M. Hosp., Parel, Bombay 400012, India). *Prog. Drug Res.* 19:147-157; 1975.

0833 A COMPARATIVE STUDY OF BITOSCANATE, BEPHENIUM HYDROXYNAPHTHOATE AND TETRACHLORETHYLENE IN HOOKWORM INFECTION. (Eng.) Johnson, S. (Christian Medical Coll. Hosp., Vellore, Tamilnadu, India). *Prog. Drug Res.* 19:70-74; 1975.

0834 COMPARATIVE STUDY OF BITOSCANATE, BEPHENIUM HYDROXYNAPHTHOATE AND TETRACHLORETHYLENE IN HOOKWORM DISEASE. (Eng.) Mutalik, G. S.; Gulati, R. B. (Sassoon General Hosp., Poona, India). *Prog. Drug Res.* 19:86-89; 1975.

0835 EXPERIENCE WITH BITOSCANATE IN HOOKWORM DISEASE AND TRICHURIASIS IN MEXICO. (Eng.) Biagi, F. (Facultad de Medicina, Universidad Nacional Autonoma, Mexico). *Prog. Drug Res.* 19:23-27; 1975.

0836 CLINICAL EXPERIENCE WITH BITOSCANATE. (Eng.) Samuel, M. R. (Dept. Clinical Development, Hoechst Pharmaceuticals Ltd., Bombay, India). *Prog. Drug Res.* 19:96-107; 1975.

0837 EXPERIENCE WITH BITOSCANATE IN ADULTS. (Eng.) Patricia, A. H.; Rao, U. P.; Subramaniam, R.; Madanagopalan, N. (Madras Medical Coll., Madras, India). *Prog. Drug Res.* 19:90-95; 1975.

0838 BITOSCANATE IN CHILDREN WITH HOOKWORM DISEASE. (Eng.) Bhandari, B.; Shrimali, L. N. (R. N. T. Medical Coll., Udaipur, India). *Prog. Drug Res.* 19:6-9; 1975.

0839 TRIAL OF A NEW ANTHELMINTIC (BITOSCANATE) IN ANCYLOSTOMIASIS IN CHILDREN. (Eng.) Ahmed, S. H.; Vaishnava, S. (Safdarjang Hosp., New Delhi, India). *Prog. Drug Res.* 19:2-5; 1975.

0840 STUDIES ON SCHISTOSOMIASIS IN SAUDI ARABIA (Eng.) Arfaa, F. (Inst. Public Health Res., Univ. Teheran, P.O. Box 1310, Teheran, Iran). *Am. J. Trop. Med. Hyg.* 25(2):295-298; 1976.

0841 OBSERVATIONS ON THE LEFT SUPRACLAVICULAR LYMPH NODES IN PORTAL HYPERTENSION. (Eng.) Aboul-Enein, A. (Dept. Surgery, Univ. Alexandria, Egypt). *Med. Chir. Dig.* 4(3):145-147; 1975.

GENERAL

Regional Enteritis

0842 FAMILIAL INCIDENCE OF CROHN'S DISEASE. (Ger.) Morl, M.; Koch, H.; Rosch, W.; Fruhmorgen, P.; Zeus, J. (Stoffwechselklinik der LVA Wurttemberg, Bismarckstr. 31, 6990 Bad Mergentheim, W. Germany). *Dtsch. Med. Wochenschr.* 101 (13):493-496; 1976.

0843 THE INCIDENCE OF CROHN'S DISEASE IN CENTRAL SWEDEN. (Eng.) Bergman, L.; Krause, U. (Univ. Hosp., Uppsala, Sweden). *Scand. J. Gastroenterol.* 10(7):725-729; 1975.

0844 CHANGING CONCEPTS OF INFLAMMATORY DISEASE OF THE COLON IN CHILDREN. (Eng.) Farmer, R. G.; Michener, W. M. (No affiliation given). *Cleve. Clin. Q.* 42(4):309-311; 1975.

0845 CROHN'S COLITIS COMES OF AGE. (Eng.) Nugent, F. W. (No affiliation given). *Lahey Clin. Found. Bull.* 25(1):11-16; 1976.

0846 DYNAMIC ASPECTS OF COLONIC CROHN'S DISEASE. (Eng.) Brahme, F.; Fork, F. T. (Veterans Admin. Hosp., 3350 La Jolla Village Drive, San Diego, CA 92161). *Radiologe* 15(2):463-468; 1975.

0847 CLINICAL PATTERNS IN CROHN'S DISEASE: STATISTICAL STUDY OF 615 CASES [Abstract]. (Eng.) Farmer, R. G. (Cleveland Clinic Foundation, Cleveland, OH). *Scand. J. Gastroenterol.* 10(34):37; 1975.

0848 THE ENDOSCOPIC FINDINGS IN CROHN'S DISEAS OF THE COLON [Abstract]. (Eng.) Furugar K.; Hradsky, M. (Gastroenterology Unit, Dept. Medicine, Lasarettet, Falun, Sweden). *Scand. J. Gastroenterol.* 10(34):39; 1975.

0849 BILE ACID ABSORPTION AND WATER TRANSPORT IN THE PERFUSED ILEUM OF PATIENTS WITH REGIONAL ILEITIS (CROHN'S DISEASE) [Abstract]. (Eng. Krag, E.; Krag, B. (Gentofte Hosp., Univ. Copenhage Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10: 31; 1975.

0850 INCREASED CONSUMPTION OF REFINED CARBOHYDRATES IN PATIENTS WITH CROHN'S DISEASE. (Eng.) Martini, G. A.; Brandes, J. W. (Medizinisch Klinik der Universitat, Mannkopfstr. 1, D-3550 Marburg/Lahn, W. Germany). *Klin. Wochenschr.* 54(8): 367-371; 1976.

0851 SECRETION RATE OF INTESTINAL IMMUNOGLOBULINS AND OTHER PROTEINS IN THE PERFUSED ILEUM OF PATIENTS WITH REGIONAL ILEITIS (CROHN'S DISEASE) [Abstract]. (Eng.) Hoj, L.; Krag, E. (Gentofte Hosp., Univ. Copenhagen, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(34):38; 1975.

0852 THE DISTRIBUTION OF IMMUNOGLOBULIN-CONTAINING CELLS IN THE INFLAMED BOWEL WALL OF PATIENTS WITH CROHN'S DISEASE AND ULCERATIVE COLITIS [Abstract]. (Eng.) Baklien, K.; Brandtzaeg, P. (Rikshospitalet, Oslo, Norway). *Scand. J. Gastroenterol.* 10(34):38-39; 1975.

0853 ASCORBIC ACID DEFICIENCY IN CLINICAL DISEASE INCLUDING REGIONAL ENTERITIS. (Eng.) Gerson, C. D. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Ann. N.Y. Acad. Sci.* 258:483-490; 1975.

0854 CHOLELITHIASIS IN REGIONAL ENTERITIS [Abstract]. (Eng.) Ammann, R.; Seiler, P.; Lutolf, U.; Knoblauch, M.; Lammli, J.; Deyhle, P.; Bihrer, R.; *et al.* (Dept. Internal Medicine, Inst. Radiology and Nuclear Medicine, Univ. Zurich, Zurich, Switzerland). *Digestion* 12(4/6):282-283; 1975.

0855 EFFECT OF AZATHIOPRINE ON CELL-MEDIATED IMMUNITY IN CROHN'S DISEASE [Abstract]. (Eng.) Willoughby, J. M. T.; Gyte, G. M. L. (Lister Hosp., Stevenage, Herts, England). *Gut* 17(5):399; 1976.

0856 SALICYLAZOSULFAPYRIDINE IN INFLAMMATORY BOWEL DISEASE. (Eng.) Das, K. M.; Sternlieb, I. (Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, NY 10461). *Am. J. Dig. Dis.* 20 (10):971-976; 1975.

0857 RESULTS OF SURGERY FOR CROHN'S DISEASE. (Ger.) Deltz, E.; Hantschmann, N. (Abteilung fur Allgemeinchirurgie im operativen, Zentrum I der Universitat, Hospitalstr. 40, D-2300 Kiel, W. Germany). *Munch. Med. Wochenschr.* 118(15):465-468; 1976.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism Digestive Diseases. This specialized information medium has been initiated to fill an existing great need i the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tr Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevan to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The numb and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent o Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
amp	ampere
ATP	adenosine triphosphate
A	angstrom
BSP	sulfobromophthalein
C	degrees centigrade
cal	calories
cc	cubic centimeter
cm	centimeter(s)
dl	deciliter
DNA	deoxyribonucleic acid
ED$_{50}$	median effective dose(s)
EDTA	ethylenediamine tetraacetic acid
e.g.	for example
EEG	electroencephalogram
ESR	erythrocyte sedimentation rate
g	gram(s)
μg	microgram(s)
Hz	Hertz
hr	hour(s)
Ig	immunoglobulin(s)
i.m.	intramuscular
i.p.	intraperitoneal
IU	international unit(s)
i.v.	intravenous
kcal	kilocalorie(s)
kg	kilogram(s)
K$_m$	Michaelis constant
LD$_{50}$	median lethal dose(s)
LDH	lactic acid dehydrogenase
m	meter(s)
M	molar; mole(s)
mM	millimolar; millimole(s)
μM	micromolar; micromole(s)
ma	milliampere(s)
mCi, μCi	milli-, microcurie(s)
mEq	milliequivalent(s)
mg	milligram(s)

ml, μl	milli-, microliter(s)
mm	millimeter(s)
mOsm	milliosmolar; milliosmeter(s)
msec	millisecond(s)
mV	millivolt(s)
min	minute(s)
MTD	maximum tolerated dose
NAD	nicotinamide adenine dinucleotide
NADH	reduced nicotinamide adenine dinucleotide
NADP	nicotinamide adenine dinucleotidephosphate
NADPH	reduced nicotinamide adenine dinucleotidephosphate
ng	nanogram (10^{-9})
nm	nanometer(s)
Pa	ambient pressure
PAS	periodic acid - Schiff
pg	picogram (10^{-12})
pgEq	picogram equivalent(s)
p.o.	orally
ppb	parts per billion
ppm	parts per million
r	Roentgen
RBC	red blood cells (erythrocytes), red blood count
resp.	respectively
RNA	ribonucleic acid
s.c.	subcutaneous
sec	second(s)
SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0858 THE AUTONOMIC INNERVATION OF THE OESOPHAGUS. (Eng.) Smith, B. (No affiliation given). *Clin. Gastroenterol.* 5(1):1-14; 1976.

0859 IX. ABSORPTION OF SUGAR, FAT, AND PROTEIN IN THE UPPER INTESTINE IN RELATION TO LOADS, TRANSIT TIMES, AND THE ENDOGENOUS DILUTION. (Eng.) Johansson, C. (No affiliation given.) *Mt. Sinai J. Med. N.Y.* 43:73-83; 1976.

0860 EFFECT OF ANTRECTOMY ON ILEAL HYPERPLASIA AFTER JEJUNECTOMY IN THE RAT [Abstract]. (Eng.) Weser, E.; Hughes, W.; Tawil, T. (Univ. Texas Health Science Center, San Antonio, TX). *Clin. Res.* 24(1):46A; 1976.

0861 A NEW CONCEPT OF THE ANATOMY OF THE ANAL SPHINCTER MECHANISM AND THE PHYSIOLOGY OF DEFECATION. IV. ANATOMY OF THE PERIANAL SPACES. (Eng.) Shafik, A. (Faculty Medicine, Cairo Univ., Cairo, Egypt). *Invest. Urol.* 13(6):424-428; 1976.

0862 IN VIVO INDUCTION OF TIGHT JUNCTION PROLIFERATION IN RAT LIVER. (Eng.) Montesano, R.; Gabbiani, G.; Perrelet, A.; Orci, L. (Institut d'Histologie et d'Embryologie et Departement de Pathologie, Universite de Geneve, 1211, Geneve 4, Switzerland). *J. Cell Biol.* 68(3):793-798; 1976.

0863 HISTOCHEMISTRY OF CANINE INTRAHEPATIC BILE DUCTS [Abstract]. (Eng.) Cook, B. H.; Granger, D. N.; Granger, H. J.; Turner, M. D.; Taylor, A. E. (Univ. Mississippi Medical Center, Jackson, MS 39216). *Fed. Proc.* 35(3):382; 1976.

ABSORPTION · EXCRETION · TRANSPORT

0869 UNIDIRECTIONAL UPTAKE OF IRON ACROSS INTESTINAL BRUSH BORDER. (Eng.) Sheehan, R. G. (Veterans Admin. Hosp., Dallas, TX 75216). *Am. J. Physiol.* 231(5):1438-1444; 1976.

The significance of the uptake step by the intestinal mucosa in the control of iron absorption was investigated by measuring the unidirectional uptake of iron on proximal small intestinal segments from sodium pentobarbital anesthetized female Sprague-Dawley rats. The method employed a nonabsorbable marker of adherent incubating medium, and the studies were performed during the linear time period of instantaneous uptake. Uptake was linear over the concentration range 0.1-10 mM, from three iron complexes. The rate varied with the bioavailability of the iron in each complex. The temperature coefficient was 1.0-1.3. Uptake rates were similar in all segments of small intestine. Uptake was not increased in segments from iron-deficient animals or rats with hemolytic anemia. Cobalt did not inhibit the uptake rate. These studies demonstrate that the uptake of nonheme iron by the small intestinal mucosal cell is by passive diffusion and further indicate that the uptake step does not contribute significantly to the mucosal control of iron absorption.

0870 IONIC REQUIREMENTS FOR THE ACTIVE ILEAL BILE SALT TRANSPORT SYSTEM. (Eng.) Gallagher, K.; Mauskopf, J.; Walker, J. T.; Lack, L. (Duke Univ. Medical Center, Box 3185, Durham, NC 22710). *J. Lipid Res.* 17(6):572-577; 1976.

Taurocholate transport by everted guinea pig ileal gut sacs was studied in physiological media containing graded amounts of sodium ions. Significant uphill transport of taurocholate was observed when the bulk of NaCl was replaced by osmotic equivalents of mannitol or choline chloride. Seventy-seven percent of control transport activity was observed when 36 mEq/l of Na^+ were present in the incubation medium, with mannitol acting as the isosmotic replacement, and 74% of the control transport was retained when 31 mEq/l of Na^+ were present in the incubation medium with choline chloride acting as the osmotic replacement. Lowering the Na^+ concentration to 19 mEq/l (84% replacement of Na^+) still allowed for 69% of the uphill transport observed in the control incubations. Taurodehydrocholate transport by ileal everted sacs was more sensitive to decreased Na^+ concentrations; 29% of control transport was observed at 31 mEq/l of Na^+. A kinetic analysis comparing the transport of taurocholate with taurodehydrocholate, the triketo analogue, at different concentrations of Na^+ indicated that the apparent affinity of the transport system for Na^+ is greater in the presence of taurocholate than in the presence of taurodehydrocholate. The ability of taurodehydrocholate to depress taurocholate transport is less in media of low Na^+ concentration. *In vivo* intestinal perfusion studies demonstrated that the depression of taurocholate absorption following Na^+ removal is reversible. These results support the hypothesis that Na^+ has a physiological role in intestinal bile salt transport, and that the affinities of the anionic bile salt and the sodium cation for the transport system are cooperative, in that one enhances the binding of the other.

0871 EVIDENCE THAT PANCREATIC PROTEASES ENHANCE VITAMIN B_{12} ABSORPTION BY ACTING ON CRUDE PREPARATIONS OF HOG GASTRIC INTRINSIC FACTOR AND HUMAN GASTRIC JUICE. (Eng.) Toskes, P. P.; Smith, G. W.; Francis, G. M.; Sander, E. G. (Gainesville Veterans Hosp., Gainesville, FL 32602). *Gastroenterology* 72(1):31-36; 1977.

The mechanism by which the administration of exogenous pancreatic extract or trypsin corrects the vitamin B_{12} malabsorption in patients with pancreatic exocrine insufficiency was investigated in three patients. Crude preparations of hog gastric intrinsic factor or the patients' own previously collected gastric juices administered with labeled vitamin B_{12} did not enhance vitamin B_{12} absorption. However, when these sources of gastric intrinsic factor were incubated with three-times-crystallized preparations of insolubilized bovine trypsin or chymotrypsin, the proteolytic enzymes were removed by centrifugation, and the preparations of gastric intrinsic factor were readministered to these patients, the absorption of vitamin B_{12} was markedly enhanced. Studies of hog gastric intrinsic factor before and after exposure to proteolytic enzymes failed to show any difference on Sephadex chromatography or polyacrylamide gel electrophoresis or on its affinity for vitamin B_{12} or the ileal receptor in guinea pigs. These investigations demonstrate that: gastric intrinsic facto
as secreted by subjects with pancreatic insufficienc
or obtained from hog pyloric mucosal extracts, is ineffective in promoting vitamin B_{12} absorption in patients with pancreatic insufficiency, and incubati
of crude preparations of gastric intrinsic factor with insolubilized pancreatic proteases modified these preparations of gastric intrinsic factor in a
as yet undefined manner, allowing them to enhance vitamin B_{12} absorption.

0872 ALTERNATIVE METHODS OF ANIMAL SACRIFICE: THE EFFECT ON INTESTINAL FUNCTION IN VITR
(Eng.) Johnson, I. T. (Dept. Chemistry, Univ. Asto
in Birmingham, Gosta Green, Birmingham, B4 7ET, England). *Experientia* 32(3):347-348; 1976.

0873 RAPID DISCRIMINATION OF REWARDING NUTRIEN
BY THE UPPER GASTROINTESTINAL TRACT. (Eng.) Puerto, A.; Deutsch, J. A.; Molina, F.; Roll, P. L. (Sch. Medicine, Univ. California, San Diego, CA 92093). *Science* 192(4238):485-487; 1976.

0874 FACTORS INFLUENCING ABSORPTION AND EXCRETION OF DRUGS. V. FURTHER STUDY ON EFFECT OF POTASSIUM ION ON IN SITU RAT INTESTINAL ABSORPTION OF DRUGS. (Eng.) Kojima, S.; Miyake, J. I. MOTILITY

0911 INTRAGASTRIC PRESSURE/VOLUME RELATIONSHIP IN THE NORMAL HUMAN STOMACH. (Eng.) Stadaas, J. O. (Ulleval Univ. Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(2):135-140; 1975.

The intragastric pressure/volume relation was studied in eight healthy subjects using a large flaccid balloon sensitive to pressure variations in the stomach. Recordings of intragastric pres-

ure variations were made for 15-min periods,
tarting with the empty balloon and following each
uccessive increment of 150 ml water up to 600 ml.
ecordings were also made for each step of volume
eduction by 150 ml until the bag was empty. Basal
ressure increased gradually and slowly with volume
ncrements and fell in a reverse manner when the
tomach was emptied. Only small contractile
mplitudes were regularly seen when the balloon
as empty (3/min, 2 cm water pressure). Rhythmic
mplitudes gradually increased with volume incre-
ents, reaching their maximum with 300 to 600 ml
ater. The sum of the amplitudes increased to
aximal activity at 300 ml. The number of contrac-
ions also increased during the filling phase to
maximum frequency at 300 ml. The mean height of
mplitudes increased with augmented volume up to
00 ml. Planimetry showed increased contractile
ctivity with volume loads to a peak at 450 ml and
00 ml for filling and emptying, resp. I.v. injec-
ion of atropine sulfate (0.01 mg/kg) abolished
hythmic contractions and reduced the parameters
xpressing contractile activity almost to zero,
hereas the basal pressure was somewhat elevated.
.v. injection of insulin (0.2 IU/kg) induced
trong rhythmic contractions and increased all para-
eters of contractile activity, but had no effect
basal pressure. These results demonstrate the
sefulness of the flaccid intragastric balloon in
e study of gastric motility responses.

12 FACTORS AFFECTING CONTRACTION OF THE SMOOTH
MUSCLE OF THE GALLBLADDER--IN PARTICULAR,
E EFFECT OF CALCIUM. (Jpn.) Yoshida, M.; Kudoh,
; Sato, S. (Showa Univ. Sch. Medicine, Showa,
pan). *Showa Igakkai Zasshi* 35(2):127-132; 1975.

ntractions of guinea pig gallbladder were studied
vitro by slitting the gallbladder open along the
ngitudinal axis on the liver side, and mounting
as a flat piece in a constant temperature bath
1 C, 30 ml volume) containing Krebs solution. A
s mixture of 95% O_2, 5% CO_2 was passed through the
lution. Electrical and chemical stimulations were
fected; Ca^{2+} concentrations in the Krebs solution
re varied by replacing $CaCl_2$ by equimolar amounts
NaCl. Maximum tensions increased upon increasing
rious electrical stimulation factors: frequency,
-30 Hz; duration, 10-20 sec; and voltage, 10-60 V.
nsions increased as temperature was increased from
to 42 C, and reached a maximum about 38-40 C,
creasing thereafter. Tensions increased with
creasing Ca^{2+} concentrations, and reached a maximum
3-4 mM, decreasing thereafter. Even after 7 hr
soaking, maximum tension values from identical
ts of electrical stimulations hardly changed.
dition of tetrodotoxin (TTX: 1×10^{-7} g/ml) de-
eased maximum tension to 10% of the maximum obtain-
le in normal Krebs solution. Muscular cramping
curred upon introduction of K^{1+} (40 mM) or acetyl-
oline chloride (ACh: 1×10^{-7} g/ml) to the Krebs
lution. However, upon removal of Ca^{2+} ions from
e Krebs solution, K cramping and ACh cramping
fects disappeared after 90 min. TTX (3×10^{-7} g/ml)
d no effect on K or ACh cramping. It seems that
ternal presence of Ca^{2+} ions is necessary for
intenance of tension.

0913 EFFECTS OF PENTAZOCINE ON GASTRO-INTESTINAL SMOOTH MUSCLE.--II) ILEUM AND ODDI'S SPHINCTER. (Eng.) Teggia, M.; Perucca, E.; Tonini, M. (Inst. Medical Pharmacology, Univ. Pavia, Pavia, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(9):591-594; 1976.

Because most narcotic analgesics can produce spasm of Oddi's sphincter in man, the effect of pentazocine was studied in the rabbit ileum and Oddi's sphincter. Pentazocine produced a dose-dependent decrease in the frequency of the slow waves in isolated ileum. At concentrations ranging from 1×10^{-6} to 5×10^{-5} g/ml, pentazocine decreased the number of spikes superimposed on each slow wave and reduced the longitudinal muscle tonus. Higher concentrations increased the frequency of the large spikes and of the contractions of the circular layer. In the presence of cerulein (1.10^{-9} g/ml), pentazocine temporarily abolished both the large spikes and the cerulein-induced intraluminal pressure. The addition of piperoxan, propranolol, or methysergide (all at 1.10^{-6} g/ml) did not abolish the inhibitory effect of pentazocine, ruling out the presence of an adrenergic or serotoninergic inhibitory mechanism. In the presence of tetrodotoxin, pentazocine caused contraction of longitudinal muscle, indicating that pentazocine does not affect the acetylcholine release from the ileum. Pentazocine concentrations of up to 1.10^{-4} g/ml caused no contraction at Oddi's sphincter, and in some experiments, even increased the flow rate across the sphincter. The findings suggest that pentazocine acts directly on ileal smooth muscle and that it is not spasmogenic in the rabbit biliary tract.

0914 EFFECT OF A BARIUM MEAL ON RESTING GASTRO-OESOPHAGEAL SPHINCTER PRESSURE IN NORMAL HUMAN SUBJECTS. (Eng.) Boesby, S.; Pedersen, S. A. (Odense Univ. Hosp., DK-5000 Odense, Denmark). *Scand. J. Gastroenterol.* 11(5):521-523; 1976.

The question of whether the ingestion of an x-ray contrast medium affects the basal gastroesophageal sphincter pressure was investigated in 10 healthy subjects. The mean basal sphincter pressure was 14 mm Hg. Twenty min after the subjects ingested 250 ml of contrast medium (150 ml barium sulphate at 0.7 g/ml and 100 ml barium sulphate at 1.0 g/ml, pH 3-5), there was a temporary but significant drop in sphincter pressure (to 10 mm Hg, $p<0.01$). These results may be due to the increase in intragastric volume following the ingestion of contrast medium. In those cases in which radiological evaluation of resistance against reflux is called for, the composition and pH of the contrast medium, the time schedule, and the degree of abdominal compression must be standardized.

0915 THE EFFECT OF INTRAVENOUS INFUSION OF SYNTHETIC HUMAN GASTRIN-I ON LOWER ESOPHAGEAL SPHINCTER (LES) PRESSURE IN THE DOG AND ITS RELATION TO GASTRIN LEVEL. (Eng.) Jennewein, H. M.; Hummelt, H.; Siewert, R.; Waldeck, F. (Boehringer Sohn, Pharmaforschung Biologie, D-6507 Ingelheim/Rhein, W. Germany). *Digestion* 14(4):376-380; 1976.

To demonstrate the relation between gastrin level and lower esophageal sphincter (LES) pressure, experiments with i.v. infusions of synthetic human gastrin-I (SHG-I) were performed in 24 anesthetized dogs. Following the ingestion of meat, serum gastrin rose from a mean basal level of 80 pg/ml to a mean maximum value of 310 pg/ml, using the antibody G-62029, and from a basal level of less than 5 pg/ml to 27 pg/ml, using antibody C-5. The administration of a single i.v. injection of pentagastrin and SHG-I (1 µg/kg) led to a prompt mean increase in sphincter pressure (45 mm Hg) and in gastrin levels (to 2,071 pg/ml with antibody C-5 and to 1,997 pg/ml with antibody G-62029). The administration of a continuous infusion of SHG-I (5 µg/kg/hr) produced a temporary increase in LES tone; gastrin levels rose to about 2,000 pg/ml using both antibodies. Physiological levels of gastrin were measured only using an infusion dose of 0.5 µg/kg/hr, which was below the threshold for increasing LES pressure. The results indicate that gastrin does not play a major role in the LES pressure regulation in the dog, but it is possible that gastrin supports or modulates other hormonal, neural, or mechanical factors giving change to the LES pressure.

0946 EFFECT OF CARBENOXOLONE ON ELECTROLYTE OUTPUT OF SALIVARY GLANDS DURING NASOGASTRIC INTUBATION. (Eng.) Ivey, K. J. (Univ. Missouri Medical Center, Columbia, MO 65201). *Am. J. Dig. Dis.* 21(12):1033-1036; 1976.

The effect of carbenoxolone on the output of salivary electrolytes stimulated by a nasogastric tube was studied in four healthy volunteers. Mean values for volume and electrolyte concentrations in control studies were: volume, 121 ± 19 ml/hr; pH, 7.39; Na^+, 19 ± 5; K^+, 20 ± 1; Cl^-, 20 ± 3; HCO_3^-, 18 mEq/l; and osmolality, 71 ± 8 mOsm/kg. Mean electrolyte outputs were quite large; Na^+, 2.4; K^+, 2.4; Cl^-, 2.6; and bicarbonate, 2.2 mEq/hr. The control data indicated that in the course of gastric secretory testing, the indwelling gastric tube stimulates a salivary electrolyte output sufficient to interfere with accurate assessment of gastric ionic fluxes and gastric acid analysis. Therapeutic doses of carbenoxolone (100 mg, t.i.d.) given p.o. for 3 weeks had no effect on salivary volume, electrolyte output, or concentration. It is concluded that carbenoxolone has no mineralocorticoid effect on mixed salivary secretion. Attention to salivary secretion is recommended in all gastric secretory studies and is mandatory where low acid output is suspected.

SECRETION AND METABOLISM

Stomach

0949 IONIC PATHWAYS OF SECRETORY MEMBRANE OF FROG GASTRIC MUCOSA IN Cl^--FREE MEDIA. (Eng.) Holloman, T. L.; Schwartz, M.; Dinno, M. A.; Carrasquer, G. (Dept. Applied Mathematics, Univ. Louisville, Louisville, KY 40208). *Am. J. Physiol.* 231(6):1649-1654; 1976.

The return ionic pathways of the secretory membrane of frog gastric mucosa associated with the electrogenic H^+ pump were studied in Cl^--free media. The replacement of a 52 mM Na_2SO_4 secretory solution with a 52 mM K_2SO_4 secretory solution led to a decrease of resistance, an increase of the H^+ secretory rate, and a reversal of the potential difference. The replacement of 52 mM Na_2SO_4 with 52 mM $MgSO_4$ led to an increase in resistance and a decrease in the H^+ rate. These results provide evidence for the existence of K^+ and Na^+ pathways, the former having a lower resistance than the latter. By short-circuiting the mucosa in Mg^{2+} solutions, the H^+ rate increased to that in Na^+ solutions, ruling out the possibility that Mg^{2+} might interfere with the H^+ pump. The fact that the Mg^{2+} secretory solution, without K^+ or Na^+ did not abolish the H^+ rate suggests the presence of at least a third ionic pathway, presumably SO_4^{2-}, providing that Mg^{2+} does not penetrate the mucosa.

0950 INFLUENCE OF CHANGES OF BLOOD CALCIUM LEVEL ON BASAL GASTRIC SECRETION. (Cze.) Blahos, J.; Mertl, L.; Gregor, O.; Kotas, J (I. Vnitrni Klinika FDL, Vlasska 36, 118 33 Praha 1, Czechoslovakia). *Vnitr. Lek.* 21(5):440-445; 1975.

EDTA infusion in 11 healthy adults caused a marked decrease in the blood calcium level, accompanied by a statistically significant reduction in gastric free HCl and total acidity, in comparison with basa levels. After infusion was stopped and the calcium level began to rise again, increases in free HCl and total acidity (statistically significant) were observed. Since the decrease in the blood calcium level was induced by EDTA rather than parathyroidectomy, the decreases in gastric secretion must have been the result of the blood calcium reductio alone, and the possible influence of a reduction in the parathyroid hormone level can be excluded. Rapid calcium infusion in 10 subjects resulted in a marked increase in the blood calcium level, whic was accompanied by a statistically significant increase in gastric free HCl and total acidity in comparison with basal values. When the blood calci level decreased after the calcium infusion was stopped, gastric secretion also decreased. Althoug the mechanism of the effect of blood calcium levels on gastric secretion is not known, a brief review of the literature indicates the possible effect of calcium on vagal activity, gastrin secretion, and cellular and membrane processes of parietal cells.

0951 SC-29333: A POTENT INHIBITOR OF CANINE GASTRIC SECRETION.

(Eng.) Dajani, E. Z.; Driskill, D. R.; Bianchi, R. G.; Collins, P. W.; Pappo, R. (Dept. Biological Res., Searle Lab., P.O. Box 5110, Chicago, IL 60680). *Am. J. Dig. Dis.* 21(12):1049-1057; 1976.

The gastric antisecretory effects of SC-29333, a novel prostaglandin E_1 (PGE_1) analog, were compared to the reference standard PGE_1 methyl ester (PGE_1ME) in gastric fistula and Heidenhain pouch dogs. Secretion was stimulated submaximally by the continuous i.v. infusion of either histamine (1.0 mg/hr) or pentagastrin (4.0 µg/kg/hr). Meal-stimulated gastric secretory studies were also conducted. SC-29333 effectively inhibited volume, acid output, and pepsin secretion, in a dose-dependent manner. When administered i.v., SC-29333 was found to be approximately 30 times more potent than PGE_1ME. The ranges of active i.v. bolus doses for SC-29333 and PGE_1ME were 0.3-3.0 and 10-30 µg/kg, resp. Unlike PGE_1ME, SC-29333 was effective p.o. at doses of 10-30 µg/kg and was considerably better tolerated and longer acting than PGE_1ME at active antisecretory doses. It is concluded that SC-29333 is a potent, long-acting, orally effective inhibitor of gastric secretion in the dog.

0952 EFFECTS OF IN VIVO ADMINISTRATION OF PENTAGASTRIN, SECRETIN, AND 13-Nle-MOTILIN ON THE IN VITRO INCORPORATION OF ^{14}C-LEUCINE INTO PROTEIN OF HUMAN GASTRIC MUCOSA.

(Eng.) Mitznegg, P.; Domschke, W.; Domschke, S.; Belohlavek, D.; Sprugel, W.; Strunz, U.; *et al.* (Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-852 Erlangen, W. Germany). *Scand. J. Gastroenterol.* 11(7):657-660; 1976.

The effects of pentagastrin, synthetic secretin, and 13-norleucine motilin (13-nle-motilin) on protein synthesis were studied in human gastric mucosa; the effects of pentagastrin on protein synthesis in the duodenal mucosa were also studied. Under endoscopic control, biopsy specimens were taken from the oxyntic gland area of the stomach before and after the administration of the respective drugs. In 29 volunteers without upper gastrointestinal disease, the basal rate of [^{14}C]leucine ncorporation into mucosal protein averaged 1.2 ± 7.7 x 10^3 counts per min/mg protein. ne and four hr after the s.c. administration f pentagastrin (6 µg/kg), values were significantly ncreased ($p<0.05$) by 18.9 and 21.8%, resp., over he basal level. One hour after an i.v. injection f secretin (2 clinical U/kg), gastric mucosal rotein synthesis was not substantially inhibited, hereas a 1-hr continuous i.v. infusion of 13-nle-otilin (0.4 µg/kg/hr) significantly decreased [^{14}C]leucine incorporation rates by 17.5% ($p<0.05$). One hour after the s.c. administration of pentagastrin, protein synthesis in human duodenal mucosa was not altered, which differs from the response previously reported in the rat. The results indicate that pentagastrin has a trophic influence on gastric mucosa in man. Gastrin and motilin may be involved in the regulation of human gastrin mucosal protein synthesis.

0953 EFFECT OF SECRETIN, GLUCAGON AND DUODENAL ACIDIFICATION ON BOMBESIN-INDUCED HYPERGASTRINEMIA IN MAN.

(Eng.) Basso, N.; Giri, S.; Lezoche, E.; Materia, A.; Melchiorri, P.; Speranza, V. (Istituto II Pathol. Chir., Policlinico Umberto I, Universita' di Roma, 00161 Rome, Italy). *Am. J. Gastroenterol.* 66(5):448-451; 1976.

The effects of duodenal acidification and of continuous infusion or a single i.v. bolus injection of secretin or glucagon were studied in 18 healthy subjects with bombesin (BBS)-induced hypergastrinemia. The subjects received BBS (15 ng/kg/min, i.v.) over a 90-min period. The continuous infusion of secretin (1.7 U/kg/hr) or glucagon (50 ng/kg/min) during the last 45 min of the BBS infusion did not significantly alter the BBS-stimulated serum gastrin levels (mean levels, 165 and 210 pg/ml in 6 subjects that subsequently received glucagon and 6 that received secretin, resp.). The same was true when the duodenum was acidified by the infusion of 0.1 N HCl (5 ml/min) in the six remaining subjects. The bolus injection of glucagon (1 mg) significantly decreased the mean serum gastrin level from a peak level of 190 pg/ml after bombesin administration to 90 pg/ml. The bolus injection of secretin (1.7 U/kg) significantly decreased the mean serum gastrin level from 180 pg/ml to the pre-bombesin level of 90 pg/ml. The fact that BBS-stimulated gastrin secretion is not inhibited by the continuous infusion of glucagon or secretin may support the hypothesis that BBS is not physiologically present in the digestive system.

SECRETION AND METABOLISM

Pancreas

981 EFFECTS OF EXOCRINE AND ENDOCRINE RAT PANCREAS OF LONG-TERM ADMINISTRATION OF CK-PZ (CHOLECYSTOKININ-PANCREOZYMIN) OR SYNTHETIC CTAPEPTIDE-CCK-PZ. (Eng.) Ihse, I.; Arnesjo, B.; undquist, I. (Dept. Surgery, Univ. Lund, Lund, weden). *Scand. J. Gastroenterol.* 11(5):529-535; 976.

he effects of repeated s.c. injections of equivalent oses (2 Ivy dog units) of commercial (10% pure) choleystokinin-pancreozymin (CCK-PZ) and of the synthetic -terminal octapeptide of CCK-PZ on exocrine and endorine rat pancreas were studied. Male Wistar rats ere treated with one of the hormones for 10 days. ats treated with the commercial CCK-PZ and with the ctapeptide had an increased wet weight of the panreas. Pancreatic concentrations of amylase, lipase, nd trypsinogen increased in a parallel fashion after oth kinds of hormonal treatment. Rats treated with he commercial CCK-PZ preparation displayed a lower nsulin response following an i.v. glucose load. The lucose tolerance, however, was slightly improved. he octapeptide treatment induced no alterations of he insulin or glucose levels after similar glucose oads. The insulin content and the concentration of rotein in pancreatic tissue or glycogen in liver nd muscle tissue were unaffected by both treatments.) difference was found on glucose utilization in uscle tissue *in vitro*. It is concluded that equiotent doses of the synthetic octapeptide and the 10% pure CCK-PZ preparation induce a similar and parallel increase of the concentrations of all three exocrine pancreatic enzymes. The inhibitory effect on glucose-induced insulin release exerted by the 10-day treatment with commercial CCK-PZ, but not by the octapeptide, is conceivably due to peptide impurities in the commercial CCK-PZ and/or to parts of the CCK-PZ molecule other than the C-terminal octapeptide.

0982 EFFECT OF NICOTINE ON SERUM SECRETIN AND EXOCRINE PANCREATIC SECRETION. (Eng.) Boden, G.; Shore, L. S.; Essa-Koumar, N.; Landor, J. H. (Temple Univ. Health Sciences Center, 3401 N. Broad St., Philadelphia, PA 19140). *Am. J. Dig. Dis.* 21(11):974-977; 1976.

Because of reports that nicotine markedly depresses exocrine pancreatic responses to exogenous secretin and to intestinal acidification, the effect of nicotine (100 μg/kg/hr) on serum secretin and pancreatic secretions was studied in dogs with chronic pancreatic fistulas. The release of immunoreactive secretin (IRS) was stimulated by the intraduodenal infusion of HCl (9.6 mEq/30 min). Pancreatic flow rate and bicarbonate and protein secretions were stimulated either by intestinal acidification or infusion of exogenous secretin (1.0 IU/kg/hr). Nicotine delayed the appearance of peak IRS concentrations in response to intraduodenal HCl by about 20 min; however, it had no effect on the total amount of IRS released, nor was this delay accompanied by a similar delay in the appearance of peak bicarbonate output. Furthermore, nicotine did not affect pancreatic secretory function stimulated by either HCl or exogenous secretin. These data do not support the hypothesis that nicotine plays an important role in the pathogenesis of duodenal ulcers in smokers by inhibiting the pancreatic secretion of bicarbonate.

0983 EFFECT OF IRRADIATION ON THE CANINE EXOCRINE PANCREAS. (Eng.) Pieroni, P. L.; Rudick, J.; Alder, M.; Nacchiero, M.; Rybak, B. J.; Perlberg, H. J., Jr.; Dreiling, D. A. (Mount Sinai Sch. Medicine, City Univ. New York, 5th Ave. and 100th St., New York, NY 10029). *Ann. Surg.* 184(5):610-614; 1976.

The short- and long-term effects of irradiation on the pancreas were studied in six dogs receiving a dose equivalent to that given to patients with Hodgkin's disease (4,000 R/6 weeks; nominal standard dose, 1,175 rets). After control secretory, histologic, and pancreatographic studies, six Thomas fistula dogs were subjected to a 2,400-R tumor dose over 2 weeks. There was a biphasic response to secretin alone or secretin with cholecystokinin-pancreozymin. An initial hypersecretion occurred at 2 weeks; the volume was increased, but bicarbonate and enzyme output remained unchanged. Thereafter there was a progressive reduction in volume, bicarbonate, and enzyme outputs (>90% after 3 months). Early ductal reduplication, but with progressive fibrosis, was detected, features compatible with chronic pancreatitis. Pancreatic insufficiency may contribute to postirradiation gastrointestinal symptoms. Close field irradiation of the pancreas results in actual destruction of the parenchyma.

SECRETION AND METABOLISM

Hepatobiliary Tract

003 HEPATIC BILE FORMATION (FIRST OF TWO PARTS). (Eng.) Javitt, N. B. (New York Hosp.-ornell Medical Center, 525 E. 68th St., New York, NY 10021). *N. Engl. J. Med.* 295(26):1464-1479; 1976.

he generation of bile water flow and the hepatic ransport of bile acids, bilirubin, and related organic anions (from miscellaneous compounds in the aily diet or medications) are reviewed. The microirculatory hepatic unit that has functional importance ithin the liver acinus is illustrated, and its opertion is described. The central problem of bile formation is understanding the mechanisms that generate ulk movement of water into the bile canaliculi. ata suggest that water flow occurs in response to smotic gradients. Studies of water flow in the ephron show that mannitol, which is distributed in liver-cell water, reflects glomerular filtration accurately. Estimation of the mannitol output in urine, compared to the plasma concentration, indicates total water flow across the glomerular membrane, and the urine-to-plasma ratio indicates the fraction of water reabsorbed distal to the glomerulus. The presence of mannitol in liver-cell water has been postulated as a result of entry via pores, via a specialized transport system in the membrane, or via regulation by the cytoplasmic water structure. Because of the excellent correlation between bile acid excretion and canalicular bile flow in all species, the term bile-acid-dependent canalicular bile flow was coined to describe this relation. This flow is demonstrable only at high rates of bile acid output, and its physiological basis is assumed to be related to the osmotic properties of the bile acids. A detailed analysis of the flow is given.

1004 HEPATIC BILE FORMATION (SECOND OF TWO PARTS). (Eng.) Javitt, N. B. (New York Hosp.-Cornell Medical Center, 525 E. 68th St., New York, NY 10021). *N. Engl. J. Med.* 295(27):1511-1516; 1976.

Hepatic bile formation and possible disturbances in the generation of bile flow at the molecular level are reviewed. A model of hepatic bile formation is described in which hepatocytes along a sinusoid successively extract bile acid until there is virtually none left in plasma. The load of the bile acids determines the number of participating hepatocytes, and the volume of bile generated determines the excretion rate of other organic solutes that are transported into the canaliculus by independent mechanisms. Failure of bile acid transport shuts this system down. The bile acid transport system can be sodium linked and is thus regulated by agents affecting either sodium or the obligated bile acid anions. Four categories of bile flow disturbance at the molecular level can be envisioned. One category involves genetic or acquired defects in the synthesis of carrier molecules. The second relates to energy sources needed to maintain mobile carrier activity, such as the sodium-potassium exchange pump requiring ATP and appropriate hydrolase enzymes. The third category involves changes in the permeability properties of the canaliculi and proximal ductules that normally restrict diffusion of molecules that are actively secreted. A fourth category involves metabolic alterations in bile acid synthesis affecting the generation of canalicular bile flow. Experimentally, monohydroxy bile acids such as 3α-hydroxy-5-β cholanoic acid and 3β-hydroxy-5-cholenoic acid can induce a severe cholestasis. The pathogenesis of the cholestasis is related to the insolubility of the compounds in aqueous solution, and their cholestatic effect is preventable by the simultaneous infusion of chenodeoxycholic or cholic acids.

1005 THE ROLE OF THE DIGESTIVE TRACT IN CHOLESTEROL METABOLISM. (Eng.) Lutton, C. (Laboratoire de Physiologie de la Nutrition, Batiment 447, F-91405 Orsay, France). *Digestion* 14(4): 342-356; 1976.

Recent developments in the intestinal secretion, excretion, and absorption of cholesterol (Ch) are reviewed, with emphasis on the role of the digestive tract in these functions in rats. Discrepancies between rat and man are pointed out. Feces from rats fed a diet with Ch (0.015%) as the only sterol, contain 0.5 mg/day of unabsorbed dietary Ch, 3 mg excreted fecal Ch, and 3 mg Ch synthesized by the digestive tract and secreted into the lumen. The mechanisms by which endogenous Ch (excreted and secreted) enters the small intestine are not yet clear, but several theories are presented. In man, endogenous Ch excretion is due solely to excreted fecal Ch, with no contribution from externally secreted fecal Ch. Sterols are transformed more extensively by human flora than by rat flora. Three sources of Ch are available for absorption in rats: dietary, excreted, and secreted Ch. Because of partial mixing, there could be a different Ch absorption coefficient for each source. The migration of Ch across the cell and mechanisms associated with the transfer of Ch to lymph are explored. What is known about the regulation of fecal excretion, external secretion, absorption, and synthesis of Ch is summarized. In man, the rate of Ch excretion is quantitatively as large as bile acid production, and conversion of Ch into bile acids does not seem to be affected by large amounts of Ch in the diet. New methods such as isotopic equilibrium, which measures Ch turnover rates in intact animals simultaneously, are promising, but it is not yet clear whether the mechanisms regulating Ch turnover in man are similar to those in the rat.

1006 ENZYMATIC SULFATION OF BILE SALTS. PARTIAL PURIFICATION AND CHARACTERIZATION OF AN ENZYME FROM RAT LIVER THAT CATALYZES THE SULFATION OF BILE SALTS. (Eng.) Chen, L. J.; Bolt, R. J.; Admirand, W. H. (Sch. Medicine, Univ. California, Davis, CA 94143). *Biochim. Biophys. Acta* 480(1):219-227; 1977.

An enzyme system that catalyzes the transfer of the sulfate group from 3'-phosphoadenosine-5'-phosphosulfate to bile salts was identified and characterized from rat liver. The enzyme is present in the cytosol fraction of liver cells. The apparent K_m values of the enzyme for 3'-phosphoadenosine-5'-phosphosulfate and taurolithocholate were 8×10^{-6} M and 5×10^{-5} M, resp. Enzyme activity was highest in the liver (37 U/mg protein), but was also detected in the kidney (18 U/mg). Enzyme activity was not detectable in brain, heart, spleen, intestinal mucosa, or RBC. The activity was completely inhibited by *p*-chloromercuribenzoate (1 mM), indicating that the enzyme requires a sulfhydryl group for activity. Rates of sulfation (compared to taurolithocholate as 1.0) were 1.2 with glycolithocholate and 0.27 with lithocholate. Sulfation appears to occur with both conjugated and unconjugated bile salts; however, the rate of sulfation is higher with the former than with the latter. A molecular weight of 130,000 was estimated by gel filtration, and the enzyme showed an isoelectric point of 5.3.

1007 CHOLIC ACID UPTAKE INTO ISOLATED RAT HEPATOCYTES. (Eng.) Anwer, M. S.; Kroker, R.; Hegner, D. (Institut fur Pharmakologie, Toxikologie und Pharmazie, Fachbereich Tiermedizin der Universitat Munchen, Veterinarstr. 13, D-8000 Munich 22, W. Germany). *Scand J. Clin. Lab. Invest.* 36(5):1477-1486: 1976.

To further characterize the process of hepatic uptake of unconjugated bile acid, cholic acid uptake was studied in isolated rat hepatocytes, using a centrifugal filtration technique to allow rapid sampling. Hepatocytes were found to adsorb as well as to transport cholic acid. The adsorption was characterized by a capacity of 24 nmol/mg cell protein and by an association constant of 0.59×10^3/M. Cholic acid uptake was linear with respect to concentration at or below 10 C, suggesting an unsaturable uptake process, which may represent simple diffusion and can be quantitated by a diffusion coefficient of 1.76 pmol cholic acid/min/mg protein/

µM. Above 10 C, the uptake curve was biphasic. After subtracting the unsaturable component from uptake rates at higher temperature, a curve showing saturable kinetics resulted. The apparent K_m and V values at 37 C were calculated to be 61 µM and 0.8 nmol/min/mg protein, resp. This saturable uptake process was temperature-dependent, with an activation energy of 13 kcal/mol (5.44×10^4 joules/mol), and was inhibited by oligomycin and KCN. Countertransport was demonstrated with cholic, taurocholic, and chenodeoxycholic acids (all at 1 mM). The results suggest that cholic acid is transported by an energy-dependent carrier-mediated process, in addition to simple diffusion by hepatocytes, and that the postulated carrier has affinity for other bile acids.

1008 PHARMACOLOGY OF DIHYDROXY-DIBUTYLETHER, A SPECIFIC CHOLERETIC DRUG. (Eng.) Fregnan, G. B.; Porta, R. (Istituto Luso Farmaco d'Italia, s.r.l., Via Carnia 26, I-20132 Milan, Italy). *Arzneim. Forsch.* 26(11):2116-2124; 1976.

The choleretic and general pharmacological properties of dihydroxy-dibutyl ether (DHBE) were investigated in several animal species. DHBE increased the bile flow in conscious Sprague-Dawley rats and dogs, after both p.o. (250-750 mg/kg) and i.v. (50-750 mg/kg) administration, the maximum percent increase being 45-151%. A choleretic effect was also observed after i.v. injection into anesthetized rats and guinea pigs. A dose-response relation was always obtained, the threshold dose being 25-100 mg/kg. No evidence of tachyphylaxis was observed in rats after repeated treatments. The bile hyperflow was generally accompanied by an increased excretion of the total dry residue in guinea pigs and dogs. The choleretic effect in rats was still present after pretreatment with either DL-ethionine or atropine. At low doses (25-100 mg/kg, i.v.), DHBE did not show spasmogenic and spasmolytic effects *in vivo* on the smooth muscles of the gallbladder of guinea pigs and dogs or on the stomach and intestine of mice and dogs; it constricted the pylorus sphincter of rats. At larger doses (200-400 mg/kg, i.v.), the compound showed a mild relaxing activity on Oddi's sphincter of guinea pigs and a weak spasmogenic activity on the gallbladder or small intestine. *In vitro,* it caused an unspecific antagonism against the spasm induced by acetylcholine, barium chloride, histamine, 5-hydroxytryptamine, and norepinephrine. In anesthetized rats, rabbits, and dogs, DHBE caused a moderate and short-lasting hypotension, and tachycardia. The threshold doses for these effects were two to four times greater than choleretic doses. In conscious dogs, the compound was slighly hypertensive. DHBE did not provoke important respiratory, electrocardiogram, diuretic, or antiphlogistic effects. It remains to be determined whether the spasmogenic activity of DHBE is due to a direct action on smooth muscle or is mediated by a humoral substance.

1009 MEASUREMENT OF CONJUGATED AND UNCONJUGATED BILIRUBIN IN BILE. II. A NEW THIN-LAYER CHROMATOGRAPHIC METHOD. (Eng.) Boonyapisit, S. T.; Trotman, B. W.; Ostrow, J. D.; Olivieri, P. J.; Gallo, D. (Siriraj Hosp., Mahidol Univ., Bangkok 7, Thailand). *J. Lab. Clin. Med.* 88(5):857-863; 1976.

A new thin-layer chromatographic (TLC) method is described for the measurement of conjugated (CB) and unconjugated (UCB) bilirubin in bile; the method was used to determine the percentages of CB and UCB in normal human gallbladder bile. Bile is streaked on a silica-gel plate and developed with chloroform. Bilirubin in the mobile UCB band and stationary CB band is quantitated by diazotization from the scraped gel with *p*-iodoaniline reagent. Both CB and UCB in bile yielded identical azopigment absorbance. There was no contamination of the UCB band with either CB or oxidative derivatives of bilirubin, and over 98% of added ^{14}C-UBC migrated with the mobile band. Recoveries from TLC averaged 98.2 ± 4.3% of the applied pigment; duplicates agreed within 10%, and the method accurately detected the enzymatic and alkaline hydrolysis of CB to UCB. Concentrations of UCB in nine samples of normal human gallbladder bile were less than 1.9 mg/dl and never exceeded 1.2% of the total bilirubin.

1010 STUDIES ON BIOSYNTHESIS OF HEPATIC FERRITIN AND ITS MICROHETEROGENEITY. (Jpn.) Yokota, M. (Sapporo Medical Coll., Sapporo, Japan). *Sapporo Igaku Zasshi* 43(3):146-154; 1974.

Biosynthesis of ferritin in rat liver was studied by i.p. administration of [^{59}Fe]citrate and [^{14}C]-leucine into male Wistar rats. Incorporation of [^{14}C]leucine into hepatic ferritin reached a maximum (about 10 times the initial level) 7 hr after i.p. administration of iron (ferric ammonium citrate 500 µg/100 g), and decreased thereafter; intake of ^{59}Fe increased steadily during a 24-hr period, increasing from the 7th hr on. There was hardly any incorporation of [^{14}C]leucine into mixed liver proteins during the 24-hr period. Amounts of ferritin protein and ferritin iron per 100 g body weight increased after iron administration. Ferritin protein reached a maximum 12 hr after iron administration and decreased thereafter; ferritin iron increased steadily during a 48-hr period to a fourfold increase. Isoelectric focusing of hepatic protein (pH 5.05-5.35) after i.p. administration of [^{59}Fe]citrate (10 µCi) showed three main ferritin peaks: I (Fr. 41-49), II (Fr. 50-57), III (Fr. 63-68). Optical density measurements (280 mµ) resulted in similar spectra. The iron to protein 100 ratio at these peaks ranged from 13.1 to 13.4. The ratios 6 hr after iron injection were: I, 18.3; II, 17.7; and III, 14.6. At 12 hr the ratios were: I, 11.6; II, 11.5; and III, 7.3. At 24 hr the ratios were: I, 11.9; II, 13.2; and III, 8.4. At 48 hr the ratios were: I, 15.6; II, 19.8; and III, 15.2. *De novo* synthesis of ferritin is indicated .

1011 ROLE OF THE SPLEEN IN HEPATIC DISORDERS—EXPERIMENTAL STUDY FROM THE VIEWPOINT OF ANTIGEN ANTIBODY REACTION. (Eng.) Ishii, K.; Suzuki, O.; Kiryu, Y.; Tsuchiya, M. (Sch. Medicine, Keio Univ., 35 Shinao-machi, Shinjuku-ku, Tokyo, 160 Japan). *Gastroenterol. Jpn.* 10(2):168-173; 1975.

The role of the spleen in hepatic disorders was studied in male albino rabbits. Fifteen rabbits were sensitized with homologous liver antigen solution (5 ml, i.v.) and Freund's adjuvant and were given antigen without adjuvant twice weekly for 2-40 weeks thereafter. An increase in both the number and size of Kupffer cells and spotty necroses was seen in the parenchyma, and there was an increase in fiber formation with cell infiltration in the liver mesenchyma. A marked degree of fiber formation was seen in the liver mesenchyma of nine animals given histamine (1 mg/ml, i.v., 0.5 mg/kg) for 105 consecutive days. A third group of 31 rabbits received the same dosage of histamine, combined with liver antigen solution in adjuvant, for up to 63 weeks; granulomatous changes, as well as the proliferation of plasma cells and Kupffer cell enlargement, were observed. In the parenchyma, fiber formation with round cell infiltration was seen in most animals, and there was destruction of limiting plates, closely resembling chronic active hepatitis. This progressed to cirrhosis with pseudolobulus formation. A fourth group of 11 rabbits received follicular hormone (0.3 mg/kg, i.m.) every 4 weeks and antigen solution with adjuvant for 2-16 weeks. Enlargement and proliferation of Kupffer cells was seen in the parenchyma, and destruction of limiting plates progressed to pseudolobulus formation. Serum γ-globulin increased with splenic weight in all groups. Splenomegaly was most prominent in the fourth group, and hypergammaglobulinemia was evident in this group. In eight rabbits splenectomized before sensitization with homologous liver antigen in adjuvant, there was a marked decrease in serum γ-globulin, and hypergammaglobulinemia never occurred. In eight rabbits splenectomized after sensitization, hypergammaglobulinemia was evident, and serum γ-globulin gradually increased, although there was a transient initial decrease. These experiments indicate that sensitization with histamine and homologous liver extract can result in liver injury closely resembling chronic active hepatitis, which progresses into cirrhosis. There could be a correlation between spleen weight and increased levels of γ-globulin. The results suggest that an autoallergic mechanism might be involved in chronic liver diseases.

1012 EFFECT OF COBALT ON MICROSOMAL CYTOCHROME P-450: DIFFERENCES BETWEEN LIVER AND INTESTINAL MUCOSA.

(Eng.) Correia, M. A.; Schmid, R. (Univ. California, San Francisco Medical Center, San Francisco, CA 94143). *Biochem. Biophys. Res. Commun.* 65(4):1378-1384; 1975.

The effect of cobalt on microsomal heme oxygenase (MHO) and cytochrome P-450 was studied in the liver, spleen, and intestinal mucosa of Sprague-Dawley rats. Cobaltous chloride given in a single s.c. dose (60 mg/kg) 18 hr before sacrifice or in two separate doses of 60 mg/kg each, 42 and 18 hr, resp., before sacrifice stimulated hepatic MHO activity, depressed the cytochrome P-450 content, and reduced benzpyrene hydroxylase (BPH) activity, confirming previous reports. In contrast, cobalt increased MHO activity, the cytochrome P-450 content, and BPH activity in the intestinal mucosa. Cobalt had no effect on the spleen. The marked difference in the effect of cobalt on the liver and intestine suggests that the mechanism of the cobalt-mediated stimulation of MHO in the two tissues either differs from or is unrelated to the turnover of cytochrome P-450.

1013 STUDIES ON SUPPRESSION OF LIVER FIBROSIS: INHIBITION OF EXPERIMENTAL LIVER FIBROSIS BY CARBON TETRACHLORIDE FOLLOWING TREATMENT WITH ELASTASE.

(Jpn.) Fukuhara, M. (Nara Medical Univ., Nara, Japan). *Nara Igaku Zasshi* 26(3):198-209; 1975.

Male Sprague-Dawley rats were injected with 50% CCl_4-olive oil solution (0.3 ml/100 g body weight, twice a week, s.c.) to produce liver fibrosis. Elastase from pig pancreas (elastoproteinase, purity 100%: saline solution, 0.4 mg/100 g body weight; s.c. injection every day) was administered concurrently, sequentially, or not at all, with the CCl_4 injections. Nodule formation on the liver surface did not occur, even after 15-20 weeks, and liver cirrhosis was absent when elastase and CCl_4 were given concurrently from the beginning. Formation of liver hydroxyproline (HOP) and acid mucopolysaccaride (AMPS) was inhibited. In the recovery phase (RECP) from liver fibrosis, liver HOP remained at low levels with elastase treatment and accelerated fibrocrasia. Elastase did not affect activity of lysosomal enzymes (cathepsin, β-glucuronidase, collagenolytic activity) in the developmental phase (DEVP) of liver fibrosis. During RECP, cathepsin activity was higher in the elastase group; collagenolytic activity was higher in the nonelastase group. Incorporation of [^{14}C]glycine into liver insoluble collagen was not affected by elastase during DEVP. Turnover of liver insoluble collagen was faster in the elastase group. Disk electrophoresis observations of elastase activity on collagens extracted from guinea pig skin showed disappearance of the β-component, and presence of the α-component. The nonspecific proteolytic action of elastase seems to accelerate dissolution of collagen telopeptide, and degradation is dominant over synthesis.

1014 IMPAIRED GANGLIOSIDE SYNTHESIS IN RAT LIVER AFTER D-GALACTOSAMINE ADMINISTRATIO IN VIVO.

(Eng.) Rupprecht, E.; Hans, C.; Leonard, G.; Decker, K. (Firma K. Thomae, D-7950 Biberach/Ris W. Germany). *Biochim. Biophys. Acta* 450(1):45-56; 1

The effect of D-galactosamine (GalN) treatment on gl cosphingolipid synthesis was investigated in female Wistar rats. Hepatitis was induced by a single dose of GalN (1.85 mmol/kg, i.p.); physiological saline w used for controls. 1-[^{14}C]galactose was injected 2 after GalN, and the specific radioactivities of the glycosphingolipid precursors, uridine diphosphate (UDP)galactose and UDPglucose, were determined. Although the time course of UDPgalactose formation was nearly identical in treated and control rats, the absolute specific radioactivity in the treated anima was four times higher. The corresponding ratio for UDPglucose was 0.85:1. The specific radioactivities of the glycosphingolipids were measured 4 hr after 1-[^{14}C]galactose injection. The radioactivities of glucosylceramide (G_{L1}) and hematoside (G_{M3}) were almost the same with and without GalN pretreatment. The labeling of G_{M1} and G_{D1}, however, was decreased to <0.1 in treated livers, suggesting that their synthesis was inhibited. The specific radioactivities of glucose and galactose obtained from individual glycosphingolipids were also determined. In GalN-treated livers, the labeling of G_{L1} was not altered, and only a small change of G_{M3} could be detected, but the rate of G_{M1} and G_{D1} synthesis was ≤5% at 2, 3, and 4 hr after galactose injection. The results demonstrate an inhibition of ganglioside biosynthesis during the development of GalN injury.

1015 EFFECT OF D-GALACTOSAMINE ADMINISTRATION ON NUCLEOTIDE AND PROTEIN METABOLISM IN ISOLATED RAT KUPFFER CELLS. (Eng.) Hofmann, F.; Wagle, S. R.; Decker, K. (Biochemisches Institut an der Medizinischen Fakultat der Universitat Freiburg, Hermann-Herder Strasse 7, D-7800 Freiburg, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 357(10):1395-1400; 1976.

The effects of D-galactosamine (GalN) administration on uracil nucleotide contents and amino acid incorporation were compared in isolated Kupffer (K) cells and hepatocytes (H) of female Wistar rats. As determined by leakage of enzymes into the incubation medium and the formation of uridine triphosphate (UTP) from uridine, the K cells had a high degree of metabolic competence and viability for at least 180 min. The nucleotide contents of the K cells were lower than those of the H. When both cells were incubated with 4 mM GalN, the uridine triphosphate and uridine diphosphoglucose contents were reduced, but the effect was much smaller in the K cells. This is apparently due to low activity of the enzymes of the galactose pathway and, therefore, to a slower rate of UDP/GalN synthesis in the K cells. This interpretation was substantiated by the low rate of UDP/GalN formation (4.5 nmol/hr/g wet weight) by the K cells in the presence of 5.5 mM D-galactose. The same results were obtained when cells were isolated from GalN-pretreated animals (1.85 mmol/kg, i.p.). The incorporated radioactivity from U-[^{14}C]leucine and U-[^{14}C]aspartate was reduced to 35% in H treated with 1 mM GalN, but to only 60% in K cells. This difference was even more striking during the first hour--amino acid incorporation into H was reduced to 50%, but that into K cells was only slightly affected, if at all. Any role that K cells may play during the development of GalN hepatitis is not a result of direct action of the amino sugar on these cells.

1016 EFFECT OF 4-METHYLUMBELLIFERONE ON THE OXIDATIVE METABOLISM OF LIVER MITOCHONDRIA IN JAUNDICED RATS AND ITS RELATIONSHIP TO CHOLERETIC ACTION. (Eng.) Yamada, T.; Ohshita, M.; Ozawa, K.; Takasan, H.; Honjo, I. (Kyoto Univ. Sch. Medicine, Kyoto, Japan). *Arzneim. Forsch.* 26(11):2040-2042; 1976.

The effect of 4-methylumbelliferone (4-MU) on the oxidative metabolism of liver mitochondria and its relation to choleretic action were investigated in 40 bile duct-ligated Wistar rats and 40 rats after biliary decompression. The oxidative metabolism of liver mitochondria fell rapidly to 50% of controls within 7 days after bile duct ligation, whereas that in rats that received 4-MU as 0.8% of their diet for 7 days fell only slightly. The effect of 4-MU on the liver mitochondrial metabolism was most prominent when it was administered to rats after biliary decompression. In rats fed 4-MU, the depressed oxidative metabolism of cholestatic liver mitochondria recovered rapidly toward normal with accelerated amelioration of serum total bilirubin. In rats without 4-MU, serum bilirubin levels remained at a significantly higher level and jaundice continued after biliary decompression by loosening the ligation of the common bile duct. 4-MU appears to exert some stimulation or amelioration of the impaired liver mitochondrial metabolism due to jaundice, which may have a close relation to its choleretic action or effective bile excretory action.

1017 THE EFFECTS OF ACUTE AND CHRONIC ETHANOL ADMINISTRATION ON CANINE BILE SECRETION. (Eng.) Dzieniszewski, J.; Tiscornia, O. M.; Palasciano, G.; Domingo, N.; Cavarzan, A.; Teixeira, A. S.; Sarles, H. (Unite de Recherches de Pathologie Digestive, INSERM, 46 Chemin de la Gaye, 13009 Marseille, France). *Am. J. Dig. Dis.* 21(12):1037-1043; 1976.

The effects of an acute i.v. 15% ethanol infusion (1.3 g/kg for 20 min) on plateau levels of hepatic bile secretion were determined in nine dogs with gastric and duodenal fistulas. Four of the dogs had been alcohol-fed for 24 months with 50% intragastric ethanol (2.0 g/kg). Emptying of the gallbladder was induced by a continuous perfusion of secretin (0.5 clinical U/kg/hr) and cholecystokinin-pancreozymin [CCK-PZ, 8 Crick Harper-Raper (CHR) U/kg/hr] and sodium taurocholate (0.62 μmol/kg/min). In the nonalcoholic dogs, the ethanol infusion reduced the plateau values of volume (29%), bile salt concentration (55%), and output (67%) significantly, with maximum reduction occurring between 20 and 60 min after infusion. In the alcohol-fed dogs, the only significant change was a fall in volume to 25% ($p<0.05$). Bile salt concentration and output plateau values were significantly higher in the alcohol-fed dogs than in the nonalcoholic dogs. There were no differences between both groups in bile salt output, evacuation rate, or lipid composition of the gallbladder bile after a single, rapid, i.v. injection of 300 CHRU of CCK-PZ. The mechanism by which ethanol induces inhibition of bile secretion is unknown. It is suggested that it may be the result of a direct toxic action of ethanol on the enzyme and/or structural components of the hepatocytes.

1018 INDUCTION OF FATTY LIVER BY ETHANOL DRINKING IN KK AND KK-A^{y} MICE. (Eng.) Furuno, K.; Arakawa, M.; Shino, A.; Suzuoki, Z. (Biological

Res. Lab., Takeda Chemical Industries, Ltd., Yodogawa-ku, Osaka 532, Japan). *J. Nutr.* 105(10):: 1253-1262; 1975.

The induction of fatty liver in mice by liquid diets in which 25-35% of available energy was derived from ethanol was studied. KK, KK-A^y, C57BL/6J/Ta, CF1/Ta, C3H/Ta, DBA/Ta, and ICR mice were used. Four diets were used: a control T7 diet, consisting of 18% casein, 65.4% cornstarch, 10% cottonseed oil, 4% Hegsted's salt, 1.5% cellulose, 0.3% DL-methionine, 0.1% choline chloride, and 0.5% vitamin mixture; a T7-B diet, similar to T7, except for the addition of 8% hydrogenated coconut oil, 2.5% cottonseed oil, and 65% cornstarch; and diets T8 and T9, with increased casein content (25 and 30%, resp.). Liquids were either water or a 15% ethanol solution. All diets were fed for 28 weeks. The KK and KK-A^y mice were the most susceptible to fatty liver induction by ethanol, with an increase in liver fat from 18.2 to 37.1% and from 16.1 to 44.5%, resp. The ICR, C57BL/6J/Ta, and CF1/Ta strains showed some increases (0.9, 1.3, and 1.1%, resp.). Strains C3H/Ta and DBA/Ta showed little susceptibility. The KK-A^y strain was more susceptible to fatty liver induction than the KK strain. Generally, alcohol ingestion decreased food intake by 75%. There was no significant difference in plasma levels of triglycerides or immunoreactive insulin after alcohol ingestion. Fatty acid analysis after a T9 diet showed increases in palmitoleic and oleic acids and a decrease in linoleic acid. The trend towards fatty liver increased with age and was more profound in the KK-A^y strain. KK and KK-A^y mice showed greater water intake due to diabetic polydipsia. There is a possible correlation between some genetic derangement in lipid metabolism and the pathogenesis of alcoholic hyperlipemia or fatty liver.

1019 POTENTIATION OF ETHANOL FATTY LIVER IN RATS BY CHRONIC ADMINISTRATION OF NICOTINIC ACID. (Eng.) Sorrell, M. F.; Baker, H.; Tuma, D. J.; Frank, O.; Barak, A. J. (Veterans Admin. Hosp., Omaha, NB 68105). *Biochim. Biophys. Acta* 450(2):231-238; 1976.

The capacity of nicotinic acid (NA) to prevent fatty infiltration due to chronic ethanol (EtOH) ingestion in rats was studied, and the independent hepatotoxic effect of NA alone was assessed. Four groups of male Sprague-Dawley rats were fed for 28 days as follows: (1) semiliquid control diet; (2) control diet plus 50 mg/100 ml NA (approximately 150 mg/kg/day); (3) EtOH diet, control diet with EtOH substituted for carbohydrate to provide 36% of the total calories; and (4) EtOH plus NA. The growth rate of groups 1 and 2 was similar and faster than that of groups 3 and 4. NA caused a significant loss in liver weight (3.10 versus 3.38 g/100 g body weight for controls, $p<0.01$). EtOH did not alter liver weight, but it produced a significant increase in total liver protein (740 versus 680 mg/100 g for controls, $p<0.05$). NA plus EtOH, however, increased liver weight significantly above that for EtOH alone (4.18 g, $p<0.001$) and potentiated the increase in total liver protein produced by EtOH alone (830 mg, $p<0.02$). Blood EtOH levels were unaffected by NA, even though NA was well-absorbed and stored in the liver. Chronic EtOH ingestion increased hepatic levels of triacylglycerol (TAG), phospholipid (PL), and cholesterol esters (ChE). NA alone significantly increased the levels of hepatic TAG and ChE. In group 4, however, NA potentiated the hepatotoxic effect of EtOH by further increasing the hepatic levels of TAG, PL, free Ch, and ChE. NA with or without EtOH was accompanied by low plasma TAG levels, suggesting a possible inhibition of hepatic lipid transport.

1020 DIAZEPAM, ETHANOL AND DRUG METABOLIZING ENZYMES IN RAT LIVER. (Eng.) Vorne, M. S.; Puolakka, J. O.; Idanpaan-Heikkila, J. E. (Dept. Clinical Chemistry, Univ. Oulu, 90220 Oulu 22, Finland). *Arch. Int. Pharmacodyn. Ther.* 216(2): 280-287; 1975.

The effect of diazepam and/or ethanol treatment for 7 days on the drug metabolizing enzymes in rat liver microsomes was studied. Twenty-four male Sprague-Dawley rats were divided into four groups: group I served as controls; group II was given 80 mg/kg diazepam/day in carboxymethylcellulose medium; group III was given 15% (v/v) ethanol in drinking water; and group IV was given both diazepam and ethanol. Diazepam and ethanol together had a depressing effect on body weight. Ethanol alone caused a significant decrease in relative liver weights, but this effect was prevented by simultaneous diazepam treatment. Diazepam metabolism was not significantly affected in any group. The cytochrome P-450 level was increased from 13.2 to 21.6 nmol/g liver in group IV. Diazepam alone and with ethanol decreased 3,4-benzpyrene activity from 6.35 to 3.91 and 4.40 nmol/g liver/hr, resp. Only ethanol alone or with diazepam increased N-methylaniline activity from 1.17 to 1.34 or 1.69 μmol/g liver/hr. *p*-Nitrobenzoic acid reduction was inhibited by both diazepam and ethanol, but the effect was not additive when the drugs were used together. The cross-tolerance effect on metabolism of diazepam after chronic ethanol ingestion may be a type of central nervous system adaptation.

1021 INSULIN REQUIREMENTS FOR HEPATIC REGENERATION FOLLOWING HEPATECTOMY. (Eng.) Yamada, T.; Yamamoto, M.; Ozawa, K.; Honjo, I. (Kyoto Univ. Sch. Medicine, Sakyo-ky, Kyoto, Japan). *Ann. Surg.* 185(1):35-42; 1977.

On the basis of changes in the adenine nucleotide and mitochondrial metabolism of the remnant liver, insulin requirements for hepatic regeneration were studied in diabetic Wistar rats treated with varying amounts of a 2.8% solution of alloxan (35, 49, 63, or 70 mg/kg, i.v.). Mildly diabetic rat with less than 30% inhibition in maximal portal insulin response to a p.o. glucose load showed a parabolic glucose tolerance pattern and could tolerate partial hepatectomy. In contrast, severely diabetic rats with more than 45% inhibition showed a linear glucose tolerance pattern and died within 24 hr after partial hepatectomy. In the former rats, the energy charge (ATP + ½ADP/ATP + ADP +

MP) levels of the remnant liver decreased slightly
oon after partial hepatectomy but could be rapidly
estored to normal levels with a concomitant rise
f oxidative phosphorylation in remnant liver mito-
hondria. The energy charge levels in the latter
roups fell more markedly and could not be restored
ecause of insufficient enhancement of mitochondrial
idative phosphorylation. An enhancement in mito-
hondrial phosphorylative activity of the remnant
ver following partial hepatectomy may be inhibited
proportion to the severity of impaired insulin
cretion, resulting in a decrease of the potential
nctional capacity of liver.

22 CORRELATION BETWEEN SERUM HIGH DENSITY
LIPOPROTEIN CONTENT AND LIVER FUNCTION
RING EXPERIMENTAL HEPATIC DEGENERATION AND RE-
NERATION. (Eng.) von Lehmann, B.; Grajewski, O.;
ntz, H. R.; Oberdisse, E. (Pharmakologisches
stitut der Freien Universitat, Thielallee 69-73,
00 Berlin 33, W. Germany). *Acta Hepatogastroenterol.*
tuttg.) 23(5):328-333; 1976.

experimental model of liver damage by i.v. injec-
on of 10 mg/kg praseodymium nitrate into female
star rats was used to compare the time course of
ver degeneration and regeneration with that of serum
gh-density lipoprotein (HDL) content. Serum HDL
ntent rapidly decreased to a minimum 24 to 48 hr
ter injection of praseodymium, returning to control
lues after 4 days. The time course of the total li-
d content behaved similarly. Liver degeneration was
racterized by SGOT, SGPT, and serum sorbitdehydro-
nase activities and by hepatic spermidine concentra-
n, nuclear RNA polymerase reactions, and ribosomal
tein synthesis. The serum enzymes began to increase
er 24 hr, and reached a maximum after 48 hr. The
racellular parameters decreased maximally within the
st 24 hr. Although they returned to control values
er 72 hr, the enzymes still showed activities around
00 mU/ml at this time. Liver regeneration was
racterized by ornithine decarboxylase, deoxycyti-
ate deaminase, and thymidine kinase activities and
rescine concentrations. The time course of these
ameters showed that regeneration was maximum after
days. The findings indicate that serum HDL content
relates well with the time course of the parameters
degeneration and regeneration and that it represents
functional state of the liver.

3 APPLICABILITY OF ICG CLEARANCE AND
EXTRACTION RATIO AS LIVER FUNCTION TESTS

SECRETION AND METABOLISM

Intestine

1084 THE PRESENCE OF AROMATIC L-AMINO ACID DECARBOXYLASE IN CERTAIN INTESTINAL NERVE CELLS. (Eng.) Costa, M.; Furness, J. B.; McLean, J. R. (Sch. Medicine, Flinders Univ. South Australia, Bedford Park, South Australia 5042, Australia). *Histochemistry* 48(2):129-143; 1976.

Neurons containing aromatic l-amino acid decarboxylase (AADC) were sought in the intrinsic plexuses of the guinea pig small intestine by incubating segments of intestine with L-dopa (2×10^{-6} M) in the presence of an inhibitor of monoamine oxidase, pargyline (5×10^{-6} M). After such incubation, some nerve cell bodies gave a fluorescence histochemical reaction indicative of the presence of a decarboxylated product of L-dopa, probably dopamine. No fluorescence reaction occurred in the unincubated control or when the RO 4-4602 inhibitor of AADC was included in the incubation mixture. The AADC-containing cell bodies apparently do not take up and store dopamine, because fluorescence could not be detected after incubation with dopamine and a monoamine oxidase inhibitor. The AADC-containing cells were found in about half of the ganglia of the submucous plexus of the guinea pig small intestine, but were found less frequently in the myenteric plexus. They were also found in both enteric plexuses of the guinea pig distal colon and of the small intestines of rabbits and rats.

1085 HYDROLYSIS OF PEPTIDES WITHIN LUMEN OF SMALL INTESTINE. (Eng.) Silk, D. B. A.; Nicholson, J. A.; Kim, Y. S. (Veterans Admin. Hosp., San Francisco, CA 94121). *Am. J. Physiol.* 231(5):1322-1329; 1976.

The quantitative significance of intraluminal peptide hydrolases in the terminal stages of peptide digestion was investigated in Wistar rats, and the precise origins of these enzymes were determined. Intestinal contents and mucosae were obtained from rats anesthetized with ether. Experiments carried out on pancreaticobiliary secretions, and germfree rats showed that pancreatic and bacterial enzymes do not contribute significantly to the luminal digestion of dipeptides. Chemical assay data, thermostability studies, and the examination of electrophoretic mobilities of luminal peptide hydrolases indicated that jejunal enzymes originate predominantly in the cytoplasm of intestinal mucosal cells, whereas the brush border of mucosal cells is a major source of the enzymes in the ileum. With glycyl-L-phenylalanine and L-phenylalanyl-glycine as substrates, jejunal luminal activity was less than 2.6% of mucosal activity. Brush border peptide hydrolase activity in ileal contents, however, was 11.9% and 40.7% of mucosal brush border activity for the two substrates, resp. Luminal enzymes thus play an insignificant role in the terminal digestion of peptides in the jejunum, but have a much more important role in the ileal digestion of peptides.

1086 EFFECTS OF CHOLERA TOXIN ON CELLULAR AND PARACELLULAR SODIUM FLUXES IN RABBIT ILEUM. (Eng.) Desjeux, J. F.; Tai, Y. H.; Powell, D. W.; Curran, P. F. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Biochim. Biophys. Acta* 448(2):352-367; 1976.

The effects of cholera toxin on the cellular and paracellular pathways of Na$^+$ movement were studied in rabbit ileum. Unidirectional Na$^+$ fluxes were examined as functions of applied potential in control tissues and in tissues from the same animal treated with purified cholera toxin. Treatment of ileum *in vitro* with toxin stimulated the cellular component of serosa-to-mucosa Na$^+$ flux (from 2.41 ± 0.49 μEq/hr/cm^2 under control conditions to 4.71 ± 0.43 μEq/hr/cm^2 after treatment with toxin, $p<0.01$). Cholera toxin had no apparent effect on Na$^+$ movement through the cells from mucosa to serosa. A marked decrease in the Na$^+$ permeability ($p<0.01$) and no detectable significant changes in transference number for Na$^+$ of the paracellular shunt pathway were observed following treatment with cholera toxin. These results provide direct evidence for the hypothesis that purified cholera toxin stimulates active sodium secretion, but has minimal effect on sodium absorption.

1087 EFFECT OF EXTENSIVE RESECTION OF SMALL INTESTINE ON THE ENTEROCHROMAFFIN CELLS OF THE REMAINING INTESTINAL SEGMENT. (Eng.) Drews, M.; Gawronski, M. (Medical Acad. Poznan, Poznan, Poland). *Pol. Med. Sci. Hist. Bull.* 15/13(5/6):613-617; 1975.

GENERAL

1102 TRITIATED THYMIDINE AUTORADIOGRAPHIC STUDY OF CELL MIGRATION RENEWAL IN THE PYLORIC MUCOSA OF GOLDEN HAMSTERS. (Eng.) Hattori, T.; Fujita, S. (Kyoto Prefectural Univ. Medicine, Kawaramachi-hirokoji, Kamikyo, Kyoto, Japan). *Cell Tissue Res.* 175(1):49-57; 1976.

The kinetics of cell proliferation, migration, and renewal in the pyloric mucosa of golden hamsters were studied by flash, cumulative, and pulse labeling autoradiography following [^{3}H]thymidine injections. Flash labeling autoradiography showed that the labeled epithelial cells were exclusively confined to a zone several cells wide in the region of the isthmus between the gastric pits and the pyloric glands. The cumulative and pulse labeling experiments showed that this cell proliferation in the isthmus region was involved in the replacement of both the surface epithelial and the glandular cells. The surface epithelial cells of the pyloric mucosa arising in the upper portion of the isthmus lined the pits and the surface and were sloughed off into the gastric lumen within a week. The mucin-containing glandular cells, which arose more deeply in the isthmus region, migrated downwards and were apparently lost at the deepest level of the glands. The life span of the mucin-containing glandular cells was estimated at about 14 days. This cell type appeared to undergo renewal of the "first produced, first lost" pipe line variety. However, a small number of glandular cells survived for over 20 days (up to 30 days), suggesting the existence of a subpopulation of cells with different kinetics in the pyloric glands.

1103 EFFECT OF PROTEIN SYNTHESIS INHIBITORS ON THE ACTIVITY OF ENZYMES--CHOLESTASIS INHIBITORS--IN EXPERIMENTAL MECHANICAL JAUNDICE.

(Pol.) Kryszewski, A.; Whitfield, J. B.; Neale, G.; Moss, D. W. (Royal Postgraduate Medical Sch., London, England). *Przegl. Lek.* 32(4):411-415; 1975.

The changes in alkaline phosphatase (APH), 5-nucleotidase (5-NT), and gamma-glutamylotranspeptidase (GGTP) levels in the serum and liver of male Wistar rats with induced cholestasis due to common bile duct ligation were studied for 8 days after the onset of jaundice. The animals were sacrificed 12, 24, 48, 96, and 120 hr after the operation. They were exsanguinated, and their serum was retained. Controls were not ligated. Other animals were given cycloheximide (1 μg/g, i.p.) and actinomycin D (0.25 μg/g, i.p.), 1 hr before ligation; they were sacrificed 24 hr later. Apart from securing their serum, the livers of the second group were homogenized and their protein concentration was determined. APH, 5-NT, and GGTP showed higher liver activity after surgery, with 5-NT and GGTP being significantly increased after only 96 hr, while APH reached its maximal level after 12 hr. In serum, APH and 5'-NT attained maximal activity after 24 hr, whereas GGTP did not reach maximum within the 8-day study period. Both cycloheximide and ac-inomycin D partially inhibited APH increases in the iver and serum and significantly reduced APH ctivity in the control serum. The decreases were pos-ibly attributable to an alteration of intestinal hosphatase synthesis. The similarity of changes in hree enzymes in clinical observations of liver and iliary tract patients to those noted in the animal tudy was pointed out.

104 STUDIES ON ORGAN SPECIFIC ANTIGENS OF THE COLONIC MUCOSA: THE RELATIONSHIP F COLON SPECIFIC ANTIGENS TO ULCERATIVE COLITIS.

Jpn.) Kuroe, K. (Hirosaki Univ. Sch. Medicine, irosaki, Japan). *Hirosaki Igaku* 27(3):504-522; 975.

Sera of patients with ulcerative colitis were studied from the standpoint of organ-specific antigens of the colon. Reactions of the rabbit sera treated with antisera of rat colonic mucosa were also examined. Water-soluble mucosal human antigens were prepared from various sections of the digestive tracts of persons with O blood type. Organ antigens from rats and rabbits were prepared from mature animals killed after being administered tetracycline (4 mg/day for 5 days, p.o.). Antisera were prepared by injecting the antigens s.c. into mature rabbits once a week for 12 weeks. Reactions between rabbit antisera and human colonic mucosa were tested with the micro-Ouchterlony method. After adsorption with human sera, liver, and gastric mucosa, the antisera formed a common precipitation line with the microsomal fraction of the human colonic mucosa and the mucosa of the small intestine. Positive immunofluorescent (IF) staining of epithelial cells of the human colon was evident. Antigen present in the microsomal fraction was common to both the colon and small intestine. In another IF antibody study, serum from rabbits immunized with rat colon extract reacted with its own colon and small intestinal mucosa. Multiple colonic hemorrhages and ulcerations occurred in 2/10 rabbits receiving saline extract injections of rat colon. Human colonic antigens were reacted with sera of 31 patients with ulcerative colitis. Positive responses not specific to ulcerative colitis occurred in five cases with the hemagglutination method (tannic acid-treated erythrocyte), in four cases with the autoimmune complement fixation test, and in two cases with IF antibody method. Data were insufficient to support the hypothesis that ulcerative colitis is an autoimmune disease.

1105 EMBRYOLOGICAL INTERPRETATION OF THE ANATOMY OF THE DIGESTIVE (ABDOMINAL) ARTERIES.

DIAGNOSTIC PROCEDURES

1177 THE RADIOLOGIC MANIFESTATIONS OF IDIOPATHIC INTESTINAL PSEUDOOBSTRUCTION. (Eng.) Schuffler, M. D.; Rohrmann, C. A., Jr.; Templeton, F. E. (Univ. Washington Sch. Medicine, Seattle, WA 98114). *Am. J. Roentgenol.* 127(5):729-736; 1976.

Six patients with idiopathic intestinal pseudoobstruction underwent extensive radiographic evaluation of the gastrointestinal tract. Two patients had mild, nonspecific gaseous distension of the small bowel, and four patients had marked small bowel and colonic distension. Propulsive motor activity was consistently absent. All patients had smooth muscle dysfunction of the esophagus, small bowel, and colon, and two patients had abnormal gastric emptying. Two forms of the syndrome were observed, characterized by either hyper- or hypoactive smooth muscle. In the hyperactive form, chaotic, spontaneous contractions of the esophagus and small intestine occurred, and extensive diverticular disease of the colon was present. In the hypoactive form, the esophagus was atonic, and there was marked widening and hypomotility of the small intestine and colon. The presence of two forms of smooth muscle dysfunction suggests that the syndrome has a heterogeneous pathology and pathophysiology.

1178 AIR CONTRAST COLON EXAMINATION IN PATIENTS WITH COLOSTOMIES. (Eng.) Goldstein, H. M.; Miller, M. H. (M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Am. J. Roentgenol.* 127(4):607-610; 1976.

A readily feasible technique for performing air contrast barium enemas in patients with colostomies is described. A number 26-30 French soft rubber catheter is inserted through the enlarged hole of an infant feeding nipple from which the tip has been cut off. A large bore needle attached to a sphygmomanometer bulb is piggybacked into the catheter. The patient is subjected to an 18-hr bowel preparation, consisting of a liquid diet, hydration, and cathartics. The patient inserts the catheter through the colostomy stoma and 6-10 inches into the descending colon. When the catheter is in position, the nipple is guided down the catheter and placed into the stoma. The patient presses the flat edge of the nipple base against the colostomy stoma to prevent barium leakage. This technique has been carried out in over 80 patients. It is well tolerated and may be completed in 30-40 min. Adequate to excellent results are obtained in all well prepared patients who are able to insert the tubing for approximately 6 inches and subsequently cooperate by maintaining manual pressure on the nipple base.

1179 GAS CHROMATOGRAPHIC ANALYSES OF INTESTINAL GAS TO CLARIFY THE QUESTION OF INERT GAS INSUFFLATION IN ELECTROSURGICAL ENDOSCOPY. (Eng.) Fruhmorgen, P.; Joachim, G. (Med. Klinik mit Poliklinik der Universitat Erlangen-Nurnberg, Krankenhausstr. 12, 8520 Erlangen, W. Germany). *Endoscopy* 8(3):133-136; 1976.

To study the necessity of inert gas insufflation for the prevention of gas explosions during electrosurgical interventions in the intestinal lumen, the concentrations of hydrogen and methane were measured by gas chromatography in 41 patients prepared in one of three ways: group 1 (10 patients), no clearing of the intestine and stimulation of the production of gas (meals of beans); group 2 (16 patients), no clearing of the intestine and no gas stimulation; and group 3 (15 patients), intestinal clearing (diet, magnesium sulfate; enemas). The explosive range of the two gases investigated was reached at a concentration of approximately 4% by volume. In group 3, the gas concentrations were lower than 0.01% in group 1 and 2, however, levels above the "explosive threshold" were measured. The findings indicate that afte careful clearing of the intestine and avoidance of dietary stimulation of gas production, there is no risk of explosion during colonic electrosurgery.

1180 GRAY SCALE CHOLECYSTOSONOGRAPHY: AN EVALUATION OF ACCURACY. (Eng.) Arnon, S.; Rosenquist, C. J. (Univ. California Sch. Medicine, Davis, CA 95616). *Am. J. Roentgenol.* 127(5): 817-818; 1976.

The accuracy of gray scale cholecystosonography was evaluated by comparing oral cholecystography and ultrasonography findings in 141 patients. Confirmation of findings by oral cholecystography or surgery was available in 123 patients, and there was agreement by cholecystosonography in 111, for an accuracy of 90%. Of 39 patients with gallstones, 30 were correctly diagnosed by ultrasound. Of the nine false negative cholecystosonograms, six had suboptimal echographic visualization of the gallbladder. Excluding these six studies, the accuracy of ultrasonic detection of gallstones was 91%. The results represent an improvement in the accuracy of gray scale ultrasonography for evaluation of the gallbladder over previous reports and demonstrate the potential usefulness of this procedure for evaluation of the nonvisualized gallbladder.

1181 LAPAROSCOPY IN THE DIAGNOSIS OF HEPATIC TUMORS. (Cze.) Charousek, J.; Cihalik, C. (Vnitrni odd. Vojenske nemocnice, Olomouc, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 29(8):541-546; 1975.

Of 67 patients with metastatic carcinoma to the liver, laparoscopy with directed liver biopsy established a correct diagnosis in 59 (88%). The diagnosis was falsely positive in three patients (4%), two of whom had macronodular cirrhosis and one of whom had focal fibrosis. Five patients (8%) showed false-negative results. In three of these, the metastases were not at all visible on the liver surface, and in two, the metastases were hidden under postsurgical adhesions. The diagnosis was correctly positive in 13 of 17 patients (76%) with primary hepatocellular carcinom and there were no false positives. Of the four patients (24%) giving false-negative results, tumors were deep in the liver tissue in two and grew infiltratively in the other two, the latter

ing cases of micro- and macronodular cirrhosis.
tastases were most often multiple and located in
th lobes (44 patients), while a solitary focus
infiltrative focal growth in only one lobe
s most often seen in hepatoma patients (10 cases).
e liver parenchyma showed signs of micronodular
rrhosis in 9 of the 13 hepatoma patients and
gns of macronodular cirrhosis in 2 patients.
paroscopy is thus of great significance in
e diagnosis of both secondary and primary
lignant tumors of the liver, and can completely
place exploratory laparotomy. Directed biopsy
a valuable supplement to endoscopic examinations.
though laparoscopic diagnosis of primary tumors
not as reliable as that of metastases, the tech-
ques are improving.

82 TECHNETIUM SCANS IN THE DETECTION OF GASTROINTESTINAL HEMORRHAGE. PREOPERATIVE
AGNOSIS OF ENTERIC DUPLICATION IN AN INFANT.

ng.) Wilson, J. P.; Wenzel, W. W.; Campbell, J. B.
resbyterian Medical Center, 1719 E. 19th Ave.,
nver, CO 80218). *JAMA* 237(3):265-266; 1977.

e case of a 3-month-old girl in whom enteric dupli-
tion of the colon causing gastrointestinal bleeding
s diagnosed by technetium scanning is presented.
e patient had a 6-week history of bright red rectal
eeding. The initial barium enema examination was
rmal. An abdominal scan after the i.v. injection
2 mCi of sodium pertechnetate ^{99m}Tc demonstrated
abnormal area of uptake in the left-upper quadrant
at appeared to be distinct from the stomach. Re-
at barium enema studies revealed irregularity of
e mucosa of the splenic flexure and filling of a
all diverticulum-like structure along the lateral
pect of the proximal descending colon. A 6 x 8-cm
plication cyst of the colon, to which a small
ount of ectopic pancreatic tissue was attached,
s removed at laparotomy. Radionuclide scanning of
e abdomen prior to routine contrast studies is
eful in the diagnosis of ectopic gastric mucosa as
source of gastrointestinal bleeding.

83 FACTOR VII AS A MARKER OF HEPATOCELLULAR SYNTHETIC FUNCTION IN LIVER DISEASE.

g.) Green, G.; Poller, L.; Thomson, J. M.;
bock, I. W. (Univ. Hosp. South Manchester, Eng-
d). *J. Clin. Pathol.* 29(11):971-975; 1976.

tor VII levels were measured in 100 patients with
er disease following parenteral vitamin K_1 ther-
, and the need for the determination of specific
tor VII in chronic liver disease was assessed.
re was good agreement between specific factor VII
surements and the one-stage prothrombin time,
ept for six patients with compensated cirrhosis
whom the prothrombin time was prolonged despite
presence of normal factor VII levels. A mean
ivity of 58% was found in patients with cirrhosis.
rhotic patients with features of hepatic decomp-
ation had a significantly lower mean level of
ivity (40%) than the "contrast" patients with
gical obstruction of the major bile ducts (93%).
ients with chronic active liver disease had mod-
te depression of factor VII levels and those with
noncirrhotic alcoholic liver damage had mean activities similar to those of the contrast group. Factor VII levels could not be correlated with BSP retention, but there was a correlation with serum albumin concentration. It is concluded that the prothrombin time, using the Quick test with a standardized thromboplastin showing good sensitivity to factor VII (e.g., the Manchester reagent), provides a reliable index of coagulability in chronic liver disease; specific factor VII assays are not indicated.

1184 THE ROLE OF METOCLOPRAMIDE IN PERORAL JEJUNAL BIOPSY: A CONTROLLED RANDOMIZED TRIAL.

(Eng.) Arvanitakis, C.; Gonzalez, G.; Rhodes, J. B. (Kansas Univ. Medical Center, Rainbow Blvd. at 39th St., Kansas City, KS 66103). *Am. J. Dig. Dis.* 21(10):880-884; 1976.

The effect of metoclopramide on p.o. jejunal biopsy was examined in a controlled, double-blind, randomized trial, and particular emphasis was placed on whether the drug affects intubation time, fluoroscopy exposure time, ease of the procedure, or patient tolerance. Forty-nine patients who required jejunal biopsy for diagnostic purposes were admitted to the study. Twenty-four patients ranging in age from 18 to 67 yr received placebo (sodium metabisulfite, i.v.), and 25 patients from 16 to 73 yr old received metoclopramide (10 mg, i.v.) prior to the jejunal intubation. Intubation time to the ligament of Treitz in the placebo group was 22.3 ± 1.9 min versus 11.3 ± 1.4 min in the metoclopramide group ($p<0.001$). Fluoroscopy exposure time was 2.47 ± 0.25 in the placebo group versus 1.40 ± 0.12 min in the metoclopramide group ($p<0.001$). Subjective clinical evaluation of the operator's assessment of the procedure was based on a 0-4 scale (much easier=0, easier=1, average=2, harder=3, and much harder=4). Metoclopramide administration resulted in a significantly easier performance of the procedure ($p<0.001$), but did not influence patient tolerance. Three patients who received metoclopramide and one receiving placebo developed mild to moderate drowsiness of short duration. The results indicate that metoclopramide significantly shortens the time required for jejunal biopsy and reduces fluoroscopy exposure. Its regulatory action on gastrointestinal motility contributes to the easier performance of a valuable diagnostic procedure.

1185 USE OF DUODENAL DRAINAGE IN THE DIAGNOSIS OF ACALCULOUS GALLBLADDER DISEASE.

(Eng.) Smith, L. A.; Jagadish, B.; Anderson, H. M.; Stephenson, S. E. (Univ. Hosp., Jacksonville, Jacksonville, FL). *Am. Surg.* 42(12):893-898; 1976.

The reliability of duodenal drainage in diagnosing gallbladder disease was evaluated in 56 patients with normal acalculous oral cholecystograms and normal upper gastrointestinal studies. All patients had complaints of right upper quadrant or epigastric pain, postprandial nausea, vomiting, and flatulence. Duodenal drainage produced three bile fractions: common duct, gallbladder, and hepatic duct bile. Specimens with significant amounts of Ca bilirubinate or cholesterol crystals and bile-stained WBC were considered positive. Thirty-five patients had positive results, 32 with predominantly Ca bilirubinate crystals and 3 with predominantly cholesterol crystals; 17 had equivocal or suspicious results; and 4 had negative results. All patients underwent laparotomy and cholecystectomy. Microscopic examination showed diseased gallbladders in 35/35 positive patients, in 14/17 equivocal patients, and in 4/4 negative patients, indicating 4 false negatives. The findings were chronic cholecystitis (CC) in 25, CC with cholelithiasis in 10, CC with cholesterolosis in 5, cholesterolosis alone in 4, CC and superimposed acute cholecystitis in 3, mild CC in 6, and a normal gallbladder in 3. Excellent-to-good results were found in 96% at clinical follow-up. Duodenal drainage is concluded to be a safe, simple test that should be used as an adjunct to other procedures in diagnosing gallbladder disease.

1186 HEMOCCULT DETECTION OF FECAL OCCULT BLOOD QUANTITATED BY RADIOASSAY. (Eng.) Stroehlein, J. R.; Fairbanks, V. F.; McGill, D. B.; Go, V. L. W. (Mayo Clinic, 200 First St. SW, Rochester, MN 55901). *Am. J. Dig. Dis.* 21(10):841-844; 1976.

The results from the guaiac slide or Hemoccult (HO) test for fecal occult blood were compared with quantitative determinations of gastrointestinal loss after the i.v. administration of ^{51}Cr-labeled RBC in 80 patients. The subjects had no dietary restriction, and were referred because of clinical suspicion of gastrointestinal blood loss or complex anemia. A total of 555 stool specimens analyzed for ^{51}Cr loss were graded as negative, trace, or positive by the HO method. Of 338 specimens containing 0-2 ml/day by isotope assay, 7.4% were positive to the HO qualitative test. Loss of at least 10 ml/day in ^{51}Cr equivalent was necessary to assure that the majority of HO reactions would be positive. Of specimens containing more than 30 ml/day, 93% were positive. The ratio of ^{51}Cr-labeled RBC equivalents to stool volume and the percentage of positive HO reactions increased together. When this ratio exceeded 10%, two-thirds of the HO responses were positive. Further validation of the HO test and additional information concerning the factors that influence the sensitivity and reproducibility are necessary for the clinical application of the HO test for fecal occult blood.

1187 RADIO-ELECTROGASTRO-ENTEROGRAPHIC CORRELATIONS. (Fre.) Ecarlat, B.; Rouleau, P.; Moline, J.; Murat, J.; Martin, A. (Service de Radiologie "B", CHU Bretonneau, F 37000 Tours, France). *J. Radiol. Electrol. Med. Nucl.* 57(4):321-329; 1976.

GASTROINTESTINAL DISEASES

ESOPHAGUS

THE VALUE OF AZYGOGRAPHY IN CARCINOMA OF THE ESOPHAGUS.

(Eng.) Segarra, M. S.;
s, J. C. (Principes de Espana Hosp., Barcelona,
). *Surg. Gynecol. Obstet.* 141(2):248-250;

genographic alterations in the posterior medi-
m in the presence of esophageal carcinoma were
ed by azygography. The possible correlations
en such changes and the degree of local invasion,
esectability, and the prognosis were also
ed. Twenty-six patients with esophageal car-
a prior to surgery, and seven controls under-
azygography under local anesthesia after treat-
with diazepam (10 mg, i.m.). The contrast
a was a water solution of iodamide mezglumine
l), injected through a trocar inserted into the
rib. Films were taken with the patient's
in light inspiration. A normal azygogram
een in 17 patients. All patients underwent
ry, and resection was carried out in 14. A
age or a reduction of the vein caliber at the
of growth was seen in eight patients, and resec-
was not possible. There was a direct correla-
between the azygogram, the degree of medi-
l invasion, and the possibility of exeresis
ese eight patients. In one patient in whom
age was detected at a distance from the primary
, resection was performed, since the image was
compression by a metastatic lymph node.
tion was possible in 13 of 17 patients with
l azygograms. Total blockage or progressive re-
on of venous caliber at the actual level of the
with contralateral filling of the azygos vein
k pressure signs on azygography contraindicates
ry, since resection of the growth is not pos-
.

INITIAL ACCURACY OF ESOPHAGOGRAMS IN DETECTION OF SMALL ESOPHAGEAL CARCINOMA.

Moss, A. A.; Koehler, R. E.; Margulis, A. R.
California Sch. Medicine, San Francisco,
43). *Am. J. Roentgenol.* 127(6):909-913; 1976.

itial accuracy of radiographic diagnosis of
esophageal carcinomas was assessed, and those
es leading to false-negative and false-positive
retations were analyzed. Esophagograms of 35
ts were interpreted without knowledge of clini-
story by four diagnostic radiologists. Six
grams were of normal esophagi, 16 were of
s benign disorders, and 13 were examples of
(<3.5 cm) esophageal carcinomas. The overall
stic accuracy averaged 58%. Small esophageal
omas were initially diagnosed accurately in
cases. Of the 27% false-negative diagnoses,
e interpreted as normal and 21% as benign
alities. Esophageal lesions in the form of
tion surrounded by a mass were most often
sed correctly as carcinoma. The most common
was interpretation of esophagitis, stricture,
cerated benign lesions as carcinoma. Esopha-
hy was found to be a good screening procedure for detection of esophageal disease, but not for accurate diagnosis of small carcinomas.

1260 THE LOWER ESOPHAGEAL SPHINCTER AS A BARRIER TO GASTROESOPHAGEAL REFLUX.

(Eng.) Fisher, R. S.; Malmud, L. S.; Roberts, G. S.; Lobis, I. F. (Temple Univ. Health Sciences Center, 3401 North Broad St., Philadelphia, PA 19140). *Gastroenterology* 72(1):19-22; 1977.

To correlate lower esophageal sphincter (LES) pressure and gastroesophageal (GE) reflux, esophageal manometry and GE scintiscanning were used to study 40 consecutive patients. Serial scintiscanning was performed as the GE pressure gradient was incrementally increased. Reflux was calculated from the ratio of esophageal to gastric radioactivity. There was an inverse relation (r=-0.60, p<0.005) between GE reflux and LES pressure. Two subgroups of 10 patients were studied further. After atropine sulfate (1.2 mg, i.v.), LES pressure decreased from 11.2 ± 1.1 to 5.3 ± 0.9 mm Hg (p<0.01) at 20 min. The GE reflux index increased from 8.3 ± 2.1 to 13.4 ± 2.2% (p<.05). After bethanechol (5 mg, s.c.), LES pressure increased from 8.9 ± 0.8 to 18.5 ± 1.0 mm Hg (p<0.001) at 30 min. GE reflux decreased from 11.9 ± 2.4 to 5.8 ± 1.7% (p<0.01). GE reflux correlates with basal LES pressure by an inverse relationship. Atropine decreases LES pressure and increases reflux. Bethanechol increases LES pressure and decreases reflux. These data suggest that LES pressure is an important determinant of GE competence.

1261 EFFECT OF CIMETIDINE ON LOWER OESOPHAGEAL SHINCTER.

(Eng.) Bailey, R. J.; Sullivan, S. N.; Macdougall, B. R. D.; Williams, R. (King's Coll. Hosp., London, SE5 9R5, England). *Br. Med. J.* 2(6037):678; 1976.

To determine whether the ability of cimetidine to decrease bleeding in erosive esophagitis in fulminant hepatic failure is due to an increase in lower esophageal sphincter pressure (LESP), esophageal manometry was carried out in six normal subjects during the continuous i.v. infusion of cimetidine (150 mg). No significant difference was found at each 15-min interval for the control LESP and the LESP of infusion. However, when the values for each 15-min period were averaged, they were significantly different from the starting values. In the first 15 min, the control value fell below (p=0.0125) the starting value, while the LESP of infusion fell only slightly in five of six subjects. Cimetidine failed to cause a sustained increase in LESP, suggesting that it prevents bleeding erosive esophagitis by decreasing gastric acidity. It may have a biomedical effect in man on LESP by stimulation of the sphincter at low blood levels and a slight inhibition at high blood levels.

1262 INCIDENCE OF IRON DEFICIENCY ANEMIA IN PATIENTS WITH LARGE DIAPHRAGMATIC HERNIA. A CONTROLLED STUDY. (Eng.) Cameron, A. J. (Mayo Clinic, Rochester, MN). *Mayo Clin. Proc.* 51(12): 767-769; 1976.

To investigate the relation between diaphragmatic hernia and anemia, the incidence of anemia in 259 patients with a diaphragmatic hernia large enough to be seen on a routine chest roentgenogram was compared with that in 259 age- and sex-matched controls. Eighteen patients with diaphragmatic hernia were anemic, compared to one control subject ($p<0.001$). In 13 patients with diaphragmatic hernia and in 1 control, the anemia was caused by iron deficiency. The findings provide additional evidence that a large diaphragmatic hernia can cause anemia secondary to chronic gastrointestinal blood loss, which is usually not the result of reflux esophagitis.

1263 PATTERNS OF GASTROESOPHAGEAL REFLUX IN HEALTH AND DISEASE. (Eng.) Demeester, T. R.; Johnson, L. F.; Joseph, G. J.; Toscano, M. S.; Hall, A. W.; Skinner, D. B. (Univ. Chicago Pritzker Sch. Medicine, 950 E. 59th St., Chicago, IL 60637). *Ann. Surg.* 184(4):459-470; 1976.

To quantitate gastroesophageal reflux in a near physiologic setting, 15 asymptomatic volunteers were studied with 24-hr pH and esophageal manometry. The normal cardia was more competent supine than in the upright position. Physiologic reflux was unaffected by age, rarely occurred during slumber, and was the rule after alimentation. One hundred symptomatic patients with an abnormal 24-hr pH record (2 standard deviations above the mean of controls) were divided into three patterns of pathological reflux: those who refluxed only in the upright position (9), only in the supine position (37), and in both positions (54). Upright differed from supine refluxers by excessive aerophagia causing reflux episodes by repetitive belching. Compared to controls, symptomatic patients had excessive postprandial reflux, lower distal esophageal sphincter (DES) pressure, and less DES exposed to the positive pressure of the abdomen. Supine differed from upright refluxers by having a higher incidence of esophagitis and an inability to clear the esophagus of acid after a supine reflux episode. Compared to controls, they had a lower DES pressure. Combined refluxers had a higher incidence of esophagitis than supine refluxers. Stricture (15%) was seen only in combined refluxers. They were similar to supine refluxers in their inability to clear a supine reflux episode. Compared to controls, combined refluxers had a lower DES pressure and less DES exposed to the positive pressure of the abdomen. Forty of the 100 patients had an antireflux procedure (4 upright, 8 supine, 28 combined). It is concluded that minimal reflux is physiological. In patients with only upright reflux, aerophagia and delayed gastric emptying may be an important etiologic factor.

1264 ESOPHAGEAL SPASM: CLINICAL AND MANOMETRIC RESPONSE TO NITROGLYCERINE AND LONG ACTING NITRITES. (Eng.) Swamy, N. (Veterans Admin. Hosp., Lake City, FL 32055). *Gastroenterology* 72(1):23-27; 1977.

The effect of nitroglycerine and long-acting nitrites on esophageal spasm was studied in 8 normal control subjects and 12 patients with esophageal spasm. The objective response of the esophagus to these drugs was recorded by obtaining esophageal manometric studies and was correlated with clinical response. In seven patients with significant gastroesophageal reflux associated with spasm, the response to nitroglycerine (1/150 grain) was unpredictable, but in five patients with diffuse esophageal spasm without gastroesophageal reflux, the response was uniformly good. All of the patients who responded to nitroglycerine also responded to long-acting nitrites (erythrityl tetranitrate and isosorbide dinitrate). These patients were placed on long-term management with long-acting nitrites; they remained symptom-free from 6 months to 4 yr. None had recurrence of symptoms on this therapy. The use of nitrites in controlling esophageal spasm is less effective in patients with gastroesophageal reflux than in patients without reflux. In the absence of reflux, long-term therapy with long-acting nitrites is effective in the management of diffuse esophageal spasm. Nitrites may also be beneficial as an adjunct to antireflux therapy.

1265 REFLUX CONTROL FOLLOWING EXTENDED MYOTOMY IN PRIMARY DISORDERED MOTOR ACTIVITY (DIFFUSE SPASM) OF THE ESOPHAGUS. (Eng.) Henderson, R. D.; Pearson, F. G. (Women's Coll. Hosp., 78 Grenville St., Toronto, Ontario, Canada). *Ann. Thorac. Surg.* 22(3):278-283; 1976.

To allow a more accurate assessment of extended myotomy, Belsey hiatal hernia repair, and gastroplasty for reflux control, 34 patients with primary disordered motor activity of the esophagus were surgically treated. Seventeen patients (group 1) had extended myotomy (6-10 cm above the aortic arch to the proximal 1 cm of stomach) and Belsey repair, and 17 (group 2) had myotomy, Belsey repair, and gastroplasty. Eight group 1 patients developed severe symptomatic reflux 6-27 months postsurgery, without evidence of hernia recurrence. In two patients, the reflux was controlled by medication; one patient was lost to follow-up, but continued to experience severe reflux; and five patients required gastroplasty. At 16-month follow-up after the second operation, none of the five showed clinical or roentgenographic evidence of reflux. None of the group 2 patients developed reflux symptoms. The final results in both groups were excellent in 28 patients, good in 5 patients, and poor in the one with the continued major reflux.

STOMACH

1281 ACUTE GASTRIC MUCOSAL INJURY DURING CONTINUOUS OR INTERRUPTED ASPIRIN INGESTION IN HUMANS. (Eng.) Metzger, W. H.; McAdam, L.; Bluestone, R.; Guth, P. H. (Veterans Admin., Wadsworth Hosp. Center, Los Angeles, CA 90073). *Am. J. Dig. Dis.* 21(11):963-968; 1976.

The effect of continuous versus interrupted high-dose aspirin (ASA) administration for 14 days was evaluated in a randomized, double-blind study in eight patients with rheumatoid arthritis. Group I ingested aspirin (1.2-1.4 g, q.i.d.) for 14 consecutive days. Group II ingested an equal dose of aspirin for 10 days, placebo for 3 days, and aspirin again on day 14. Acute gastric mucosal injury was measured by histologic scoring of serial gastroscopy and gastric biopsy specimens. Significant gross mucosal damage was seen in all patients following 3 days of ASA ($p<0.01$), it persisted without significant change in severity to the end of the study. Histologic gastritis in areas free of hemorrhages and erosions was not increased significantly by ASA. In spite of gross mucosal injury, symptoms occurred infrequently. Serum pepsinogen I, but not serum gastrin, increased significantly following 3 days of ASA ($p<0.024$), and the elevation persisted to the end of the study. The mean levels of serum pepsinogen I were 159 and 147 ng/ml on days 3 and 15, resp., and only 103 ng/ml at the start of the study. The extent of mucosal injury at 14 days was not significantly different in those receiving ASA continuously from those on an interrupted schedule. Gastric mucosal adaptation to ASA in man was not demonstrated.

1282 GASTROINTESTINAL PLASMA PROTEIN LOSS DURING ETHANOL INGESTION. (Eng.)
Chowdhury, A. R.; Malmud, L. S.; Dinoso, V. P., Jr. (St. Joseph Hosp., 12th and Walnut St., Reading, PA 19603). *Gastroenterology* 72(1):37-40; 1977.

To determine the effect of ethanol ingestion on gastrointestinal protein loss, plasma and "equivalent" albumin loss in the feces were quantitated before and during ingestion of 40% ethanol using ^{51}Cr-labeled albumin. Five subjects were studied in each classification of normal gastric mucosa, superficial gastritis, and chronic atrophic gastritis. During the control period, plasma albumin loss was minimal and similar in all three groups. Exposure to ethanol resulted in a greater output of plasma albumin in the feces of all subjects. This loss was statistically significant in subjects with superficial gastritis ($p<0.01$) and chronic atrophic gastritis ($p<0.005$). Two subjects from each group underwent gastric clearance studies of ^{51}Cr-labeled albumin. Increased gastric clearance of plasma was observed in all six subjects during ethanol ingestion; the increase was highly significant in subjects with atrophic gastritis ($p<0.001$). Ethanol ingestion can cause increased loss of plasma protein in the feces, which may be of clinical significance in subjects with atrophic gastritis.

1283 CORRELATION OF HISTOLOGICAL PATTERNS OF PRIMARY GASTRIC LESIONS WITH AUTOPSY FINDINGS IN GASTRIC CARCINOMAS. (Jpn.) Nagatomo, T.; Murakami, E.; Mizuno, S.; Fujii, K. (Osaka Kosei Nenkin Hosp., Osaka, Japan). *Gan No Rinsho* 21(4):264-272; 1975.

Autopsies were performed on 123 gastric carcinoma patients, and the dominant spread of the tumor at death was determined. There were 39 curatively resected cases, 35 noncuratively resected cases, and 49 nonresected cases. The primary gastric lesions were divided into four types: localized (LOC), intermediate (INT), infiltrating (IFL: scirrhous, nonscirrhous), and muconodular (MCN). The grade of serosal rupture (s-factor), vascular invasion (v-factor), and lymph node metastasis (n-factor) was determined for each type. In LOC and INT lesions, the v-factor was predominant; hematogeneous organ metastases and lymph node metastases occurred extensively. In IFL and MCN lesions, the s-factor was predominant, and extensive peritonitis carcinomatosa occurred. The spread of the tumor and the type of recurrence did not depend on the type of resection, but correlated with the histological type of the primary gastric lesion.

1284 FAMILY PATTERNS OF ANTRO-FUNDAL GASTRITIS. (Eng.) Ihamaki, T.; Kekki, M.; Varis, K.; Siurala, M. (Meilahti Hosp., SF-Helsinki 29, Finland). *Acta Hepatogastroenterol. (Stuttg.)* 23(5): 345-350; 1976.

Family patterns of antrofundal gastritis in 311 first-degree relatives of 78 consecutive gastric carcinoma patients and 386 first-degree relatives of control probands computer-matched from a large Finnish population are reviewed. Blind and direct-vision gastric biopsies of the antrum and fundus were made, along with determinations of serum gastrin levels, circulating parietal cell antibodies, and pentagastrin secretion. Direct-vision biopsy of 288/386 control relatives showed that in 176, the state of the antral and fundal mucosa was similar (both normal or gastritic). Changes were predominant in the antral mucosa in 80 and in the fundal mucosa in 32 patients. Antral gastritis was associated with a normal fundal mucosa in only 13 patients, while the converse was true in only 18. There was a distinct accumulation of gastritis in some families, and the immunology, function, and histology of the stomach tended to be uniform within the family. Representative data are tabulated for three families. Both the A and B types of gastritis (Strickland and Mackay) and the AB type (Pitchumoni and Glass) were discernable in these series, particularly the A type, which is associated with high serum gastrin values and circulating parietal cell antibodies. The 386 controls were analyzed stochastically to obtain epidemiological evidence for the occurrence of A and B gastritis. There was a discernable A-gastritis line that deviated from the main population, but no clear-cut regression line representing B gastritis could be found.

1285 TREATMENT OF HEMORRHAGIC GASTRITIS BY ANTACID. (Eng.) Simonian, S. J.; Curtis, L. E. (Univ. Chicago Pritzker Sch. Medicine, 950 E. 59th St., Box 402, Chicago, IL 60637). *Ann. Surg.* 184(4):429-434; 1976.

A simple and safe method of nonsurgical treatment for the control of massive acute gastric mucosal hemorrhage is described. The treatment consists of complete neutralization of gastric acid with antacid to a pH of 7. The antacid is intermittently added and aspirated through a nasogastric ube to maintain the pH of the aspirate at 7. n a retrospective analysis, the hemorrhage was ontrolled in 44 of 49 patients (89%). Five atients who continued to bleed underwent surgery 10%); three had vagotomy and pyloroplasty, and neir bleeding ceased without recurrence. Two atients underwent partial gastrectomy, but ney developed recurrent bleeding and died. One atient whose bleeding has been controlled by agotomy and pyloroplasty died without hemorrhage 0 days after operation. Of the 44 patients nose bleeding was controlled by antacid, 11 ied without hemorrhage one or more weeks later. nese results of 89% control of hemorrhage compare avorably with those in the literature.

286 TRANEXAMIC ACID AND UPPER GASTROINTESTINAL HAEMORRHAGE--A DOUBLE-BLIND TRIAL.

Eng.) Biggs, J. C.; Hugh, T. B.; Dodds, A. J. St. Vincent's Hosp., Darlinghurst, N.S.W., ustralia). *Gut* 17(9):729-734; 1976.

he efficacy of antifibrinolytic therapy in the anagement of acute upper gastrointestinal emorrhage was investigated in a double-blind linical trial of 200 patients. Of these, 103 eceived antifibrinolytic therapy with tranexamic cid (amino-methylcyclohexane-carboxylic acid; g, i.v., + 1 g, p.o./8 hr for 48 hr, followed by g, p.o./8 hr for an additional 72 hr); the re- aining 97 patients received placebo only. The everity of initial blood loss, transfusion equirements, and incidences of recurrent bleeding, urgical intervention, and death were determined. he final diagnosis as to the site of bleeding as arrived at using endoscopy, barium studies, nd the findings at operation and autopsy. The roups were well matched as to severity of initial emorrhage, age, sex, etiological diagnosis, and recipitating factors. Twenty-three of 97 patients n the control group and 7 of 103 patients in the reatment group required surgery for the control f bleeding. There was reduction in the transfusion ate after the first 3 days of hospitalization n the treatment group. There were no significant ifferences in mortality or in side-effects etween the two groups. Further studies of the se of antifibrinolytic therapy in the control f gastrointestinal bleeding are warranted.

287 PROGNOSIS OF GASTRIC ULCER: TWENTY-FIVE YEAR FOLLOWUP.

(Eng.) Kraus, M.; endeloff, G.; Condon, R. E. (Wood Veterans Admin. osp., Milwaukee, WI 53193). *Ann. Surg.* 184(4): 71-476; 1976.

our hundred twenty-two patients with gastric ulcer reated during 1950-1960 were followed up to 25 yr mean follow-up, 9 yr) to assess the results of perative and nonoperative treatment and to appre- iate the propensity of gastric ulcers to recur. onoperative treatment was used in 59%, with a ospital mortality of 35%; one-third of these eaths was directly due to gastric ulcer perforation r hemorrhage. Operative treatment was used in 1% of patients. The most common operation was gastric resection without vagotomy, which was used in 86% of the cases. Overall operative mortality was 16%--34% for emergency procedures and 6% for elective procedures. Cachexia was the most important factor in operative mortality. Nonoperative treatment resulted in more than twice the hospital mortality as operative treatment. Approximately one-half of all patients treated nonoperatively had a recurrent gastric ulcer at some time during this study. The recurrence rate following definitive gastric resection was 1.3%, compared with 16% during nonoperative therapy. Three-fourths of recurrences occurred later than 2 yr, and nearly half of recurrences occurred after more than 5 yr of follow-up. Patients with a prior history of overt bleeding from gastric ulcer disease were particularly at risk for furthur bleeding. There were coincidental duodenal ulcers in 10% of the patients and there was an 0.8% incidence of gastric cancer during follow-up. Earlier elective operation in patients with overt bleeding, recurrence, or persisting symptoms should decrease overall mortality and result in a lower overall long-term risk of ulcer complications.

1288 DELAYED GASTRIC EMPTYING FOLLOWING GASTRECTOMY.

(Eng.) Cohen, A. M.; Ottinger, L. W. (Cox Building, Floor 1, Massachusetts General Hosp., Boston, MA 02114). *Ann. Surg.* 184(6):689-696; 1976.

Experience with 46 patients who were unable to take a solid diet within 2 weeks of gastric resection but had no other postoperative complications is reviewed. Five patients had undergone partial distal gastrectomy, 11 had undergone subtotal gastrectomy, and the remaining 30 had had a hemigastrectomy and truncal vagotomy. The incidence of delayed gastric emptying was found to be 2.5 times greater in patients with vagotomy and hemigastrectomy than in those with subtotal gastrectomy. In addition, postoperative delay was often prolonged in the hemigastrectomy and vagotomy group. Mechanical factors were responsible for delay in only 10% of these patients. It is suggested that localized starch peritonitis may explain many cases of "functional efferent limb ileus." Conservative management for the majority of patients is recommended. Reoperation is reserved for those who require feeding or draining enterostomy tubes and for those whose clinical course and evaluation suggest obstruction.

1289 THE PATHOGENESIS AND THERAPY OF THE POSTVAGOTOMY SYNDROME.

(Eng.) Stremmel, W. (Dept. Surgery, Univ. Freiburg, Freiburg, W. Germany). *Chir. Gastroenterol.* 10(2):159-163; 1976.

Experience with six cases of postvagotomy syndrome is reported. Two patients had severe diarrhea, and four had a moderate form. It was assumed that the diarrhea was chologenic, as previous studies have indicated, that after vagotomy, the incidence of gallstones is increased and bile composition is altered. Cholestyramine (4 g, t.i.d) eliminated the diarrhetic stools within 2-3 days, at which time the dosage was reduced (4 g/day). Steatorrhea was not observed under this therapy, but if it should occur, fat, in the form of middle-chained triglycerides, is recommended. Two other factors are postulated for the appearance of diarrhea: the increase of bacteria in the small bowel and the diminished resorption of bile acids in the terminal ileum. In addition, after vagotomy, the fasting gastrin level is markedly increased. This results in stimulation of colon motility and inhibition of bile acid resorption in the terminal ileum. Gastrin also diminishes the tonus in the ileocecal valve, making bacterial settling from the colon into the terminal ileum possible.

1333 DUODENO-GASTRIC REFLUX IN GASTRIC ULCER PATIENTS IN RELATION TO INTESTINAL METAPLASIA OF THE GASTRIC MUCOSA. (Eng.) Tympner, F.; Domschke, W.; Demling, L. (Medizinische Klinik mit Poliklinik der Universitat Erlangen-Nurnberg, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(5):360-364; 1976.

Duodenal regurgitation in 13 gastric ulcer patients and 14 healthy controls was determined quantitatively. Using vitamin B_{12} labeled with Co^{58} as an exogenous marker and bilirubin as an endogenous marker, the duodenogastric reflux was determined under basal conditions and during stimulation (1 clinical U secretin/kg + 1 clinical U pancreozymin/kg) of the exocrine pancreas. In addition, histologic examination of the gastric mucosa was carried out by taking multiple biopsies from along the greater and lesser curvatures of the stomach. In the controls, a duodeno-gastric reflux accounting for 1% of the gastric aspirate was observed in the basal phase; there was only a 1% duodenal reflux during stimulation without aspiration of the duodenal contents and a 2.5% reflux during stimulation with aspiration. In the gastric ulcer patients, the corresponding figures were 4.5%, 9.5%, and 9.2%. However, increased reflux was found only in those ulcer patients presenting with an antral metaplasia. No statistically significant increase in duodeno-gastric reflux can be verified under secretin/pancreozymin stimulation of the pancreas.

1334 ANTRAL GASTRIN REGULATION. (Eng.) Levine, B. A.; Greenburg, A. G.; Peskin, G. W.; Saik, R. P. (Veterans Hosp., San Diego, CA 92161). *J. Surg. Res.* 20(6):509-514; 1976.

The effect of pH alone and with a protein meal on gastrin release was studied in patients with duodenal ulcer, normal subjects, and in dogs. In one series, 12 patients (6 normal and 6 with ulcer) were fed a 180-g protein meal; in a second series of 18 normal subjects and 12 ulcer patients, the antral stimulant was pH buffered saline (0.1 N HCl and 0.1 N $NaHCO_3$). In dogs, antral pH was varied from acid to alkaline and alkaline to acid with solutions of HCl and $NaHCO_3$. The mean fasting serum gastrin levels were similar in normal and duodenal ulcer patients (142 ± 50 and 128 ± 38 pg/ml, resp.), while the integrated gastrin output following a protein meal was significantly greater ($p<0.005$) in the duodenal ulcer patients. Intragastric pH did not correlate with any significant changes in peripheral serum gastrin in either normal or ulcer patients. Normal subjects demonstrated some acid inhibition by regression curve analysis. Significant differences could not be appreciated if the antrum was topically perfused from low pH (1) to high pH (8) or from high to low pH. On 17 of 28 occasions, acid inhibition was noted in normal subjects, but there was a decrease in gastrin ($p=0.043$) in only 5 of 15 occasions in the ulcer group. In the animal experiments, o differences in serum gastrin levels to either ne acid or alkaline antral challenge were evident n the acute dog model, sampling from an antral vein 182 versus 170 pg/ml) or in the chronic dogs, ampling peripherally (82 versus 91 pg/ml). This tudy supports the concept that gastrin release ollowing a protein meal is significantly elevated n duodenal ulcer patients, despite lack of signifi-ant differences in basal levels.

335 THE PLACE OF GASTRIN DETERMINATION IN ULCER SURGERY. (Eng.) Sauberli, H. (Kantonsspi-al, CH-8091 Zurich, Switzerland). *Eur. Surg. Res.* (4):269-280; 1976.

he place of gastrin determination in ulcer surgery as studied in 50 duodenal ulcer patients. The role f the vagus in the gastrin response to a test meal as studied before and 3, 6, and 12 months after ighly selective vagotomy (HSV) with and without angensteen-pyloroplasty (25 patients each). Basal nd stimulated gastrin concentrations in serum, as etermined by radioimmunoassay, were elevated 3 onths after the operation, and 3 hr after the test eal, gastrin levels were still 50% higher than the asal levels. No difference was found between the atients treated with HSV alone and those treated ith HSV and additional pyloroplasty. Six and twelve onths after the operation, a moderate decrease of astrin secretion was observed, but basal and stim-lated gastrin levels were still elevated after 12 onths, compared to the values before operation. The esults indicate that the pattern of gastrin secre-ion changes as time passes after highly selective agotomy with or without additional pyloroplasty.

336 EFFECT OF GRADED AMOUNTS OF ACID INSTILLED INTO THE DUODENUM ON PANCREATIC BICARBONATE ECRETION AND PLASMA SECRETIN IN DUODENAL ULCER ATIENTS AND NORMAL SUBJECTS. (Eng:) Isenberg, . I.; Cano, R.; Bloom, S. R. (Veterans Admin. adsworth Hosp. Center, Los Angeles, CA 90073). *astroenterology* 72(1):6-8; 1977.

ecause impaired secretin release and/or bicarbonate ecretion in response to duodenal acidification ould contribute to the lower duodenal pH seen in uodenal ulcer patients, pancreatic bicarbonate ecretion and plasma secretin were measured n response to graded amounts of HCl (0.94, .88, 3.75, and 7.5 mEq/5 min) instilled di-ectly into the duodenum in nine duodenal ulcer atients and in nine normal subjects. These graded mounts of acid produced graded increases in ancreatic bicarbonate in both groups. Mean icarbonate secretion was significantly greater n the duodenal ulcer patients than in the normal ubjects basally and after the lowest dose f HCl. The mean peak 30-min bicarbonate out-ut after duodenal acidification was 3.0 ± 1.0 Eq in the duodenal ulcer patients and 2.1 ± 0.6 Eq in the normal subjects ($p<0.5$). A significant $p<0.05$) increase in plasma secretin occurred after uodenal acidification, but the increase in the uodenal ulcer and normal subjects was not significantly different ($p>0.2$). These results indicate that pancreatic bicarbonate secretion and the increase in plasma secretin in response to graded amounts of duodenal acid are at least as great in patients with duodenal ulcer as in normal subjects.

1337 RESPONSE TO JEJUNAL ACIDIFICATION IN MAN. II. PANCREATIC, BILIARY AND GASTRIC RESPONSES. (Eng.) Thjodleifsson, B.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Dundee, Scotland). *Scand. J. Gastroenterol.* 11(5):505-512; 1976.

Eight control subjects and 10 patients with duodenal ulcer underwent jejunal perfusion with a 0.05 M HCl solution (8.3 ml/min for 150 min), and the effects on bicarbonate (BC), trypsin (T), and bile pigment (BP) secretion into the duodenum were determined. During the final 75 min of acid perfusion, five controls and six patients also underwent i.v. infusion of cholecystokinin-pancreozymin and secretin (CCK/S). The outputs of BC, T, and BP in response to acid perfusion were similar in patients and controls, but there was a trend for the patients to secrete less BC than normal. After combined acid/CCK/S, the outputs of BC and BP remained similar in both groups, but the output of T was significantly greater in the patients ($p<0.05$) than in controls. The output of BC was significantly greater ($p<0.05$) in controls in response to CCK/S alone and to acid/CCK/S than in patients. In contrast, the output of T was significantly greater ($p<0.05$) in the patients in response to acid/CCK/S, but it was significantly less ($p<0.05$) in response to CCK/S. BP output with either stimulus did not differ significantly between controls and patients. There was a significant negative correlation ($p<0.001$) between the disappearance of acid from the jejunal luminal contents and the secretion of BC and T into the duodenum. The pancreatic response to acid in the duodenum was concluded to depend on exposure of the jejunal mucosa to amounts of acid that are higher than threshold in all subjects. The patients differed from controls in that they lacked an acid-released jejunal inhibitor of T secretion by the pancreas.

1338 MUCOSAL GASTRIN CONCENTRATION, MOLECULAR FORMS OF GASTRIN, NUMBER AND ULTRASTRUCTURE OF G-CELLS IN PATIENTS WITH DUODENAL ULCER. (Eng.) Creutzfeldt, W.; Arnold, R.; Creutzfeldt, C.; Track, N. S. (Dept. Medicine, Univ. Gottingen, Gottingen, W. Germany). *Gut* 17(10):745-754; 1976.

The immunoreactive gastrin (IRG) concentration, the molecular forms of IRG, and the number and ultrastructural appearance of G-cells in the antral and duodenal bulb mucosa of patients with duodenal ulcer (DU) and controls were studied. The mean antral IRG concentration of 38 DU patients was significantly higher (35.9 ± 5.2 µg/g) than that of 21 controls (15.9 ± 2.6 µg/g). The mean IRG concentration in the proximal duodenal mucosa of 15 DU patients (3.2 ± 0.8 µg/g) was not significantly higher than that of 10 controls (1.8 ± 0.5 µg/g). The number of G-cells in the antral mucosa of 58 DU patients and in the duodenal mucosa of 29 DU patients was similar to that of controls.

The distribution of immunoreactivity in gastrin components was investigated in the antral and duodenal mucosa of six DU patients and six controls. In the antral mucosa, the mean percentage of G-17 was 93.3% in DU patients and 92.0% in controls. G-34 amounted to 4.0% in DU patients and to 5.0% in controls. The G-34 percentage in the duodenal mucosa was not significantly higher in the DU patients than in the controls (50.1% versus 35.8%). Ultrastructurally, the antral G-cells of DU patients had a significantly lower density index of their secretory granules (1.43 ± 0.03 versus 2.52 ± 0.14), suggesting higher functional activity. It is concluded that the exaggerated serum IRG response of DU patients to different stimuli is not a consequence of an increased G-cell mass.

1339 EFFECT OF METIAMIDE ON BASAL AND STIMULATED SERUM CHOLECYSTOKININ LEVELS IN DUODENAL ULCER PATIENTS.

(Eng.) Spence, R. W.; Celestin, L. R.; Harvey, R. F. (Frenchay Hosp., Bristol, England). *Gut* 17(11):920-923; 1976.

To study the effect of decreasing endogenous gastric acid secretion on serum cholecystokinin (CCK) levels, CCK levels were measured in 10 patients with chronic duodenal ulcers, fasting and at intervals after two standard test meals (300 ml of 40 mM phenylalanine solution). One meal was given before and one during H_2-receptor blockade with metiamide (200 mg, q.i.d.). Fasting serum CCK levels were lower in all patients during treatment with metiamide, the mean level falling from 306.0 ± 102.0 to 82.1 ± 23.6 pg/ml after treatment ($p<0.01$). In contrast, peak serum CCK levels after the meal were not significantly different (7,400 ± 1,141 pg/ml before treatment and 7,569 ± 1,293 pg/ml on metiamide). In duodenal ulcer patients, CCK secretion under basal conditions may be, in part, dependent on stimulation of the small intestinal mucosa by gastric acid, but after an amino acid meal, gastric acid secretion is less important in determining the amount of CCK released.

1340 A COMPARISON OF THE ACID AND GASTRIN SECRETORY RESPONSES TO HYPOGLYCAEMIA AND MEALS IN DUODENAL ULCER WITH AND WITHOUT ACID HYPERSECRETION TO PENTAGASTRIN.

(Eng.) Lam, S. K.; Sircus, W. (Western General Hosp., Edinburgh, EH4 2XU Scotland). *Digestion* 14(1):1-11; 1976.

The functioning cell masses of gastrin cells (G cells) and parietal cells in two duodenal ulcer (DU) groups were compared by examining the responses to hypoglycemia-induced vagal stimulation and to standard test meals. In 60 uncomplicated DU patients, maximum acid output (MAO) after injection of 0.6 μg pentagastrin and acid output following insulin-induced hypoglycemia (IAO; 0.2 U/kg) were measured, and in 30 patients, serum gastrin responses to insulin and to standard meals were also measured. Among the 60 patients, there were 36 normosecretors with an MAO of ≤ 0.50 mmol/kg and 24 hypersecretors with an MAO ≥ 0.50 mmol/kg. The mean IAO in the hour following the insulin injection was significantly higher in the hypersecretors (20.2 ± 1.7 mmol/hr) than in the normosecretors (16.3 ± 1.1 mmol/hr) and the normal subjects (10.4 ± 1.7 mmol/hr, $p<0.025$ and 0.0025, resp.). There was a significant correlation between IAO and MAO in the normal subjects ($p<0.01$) and normosecretors ($p<0.001$), but not in the hypersecretors. In normosecretors, the serum gastrin levels at 40-120 min were significantly higher than those of hypersecretors and normal subjects. The integrated gastric response was significantly higher in normosecretors than in hypersecretors and normal subjects ($p<0.025$ and 0.01, resp.). The IAO:MA ratio was significantly correlated in normosecretors ($p<0.01$), but not in the other groups. The results show that when the vagus is stimulated, the response of the parietal cell mass in normosecretors is, to a greater extent, a reflection of the amount of gastrin released; among hypersecretors, it is predominantly the result of the large number of parietal cells being stimulated.

1341 A COMPARISON OF BASAL AND STIMULATED GASTRIC ACID AND DUODENAL BICARBONATE IN PATIENTS WITH AND WITHOUT DUODENAL ULCER DISEASE.

(Eng.) Gutierrez, L. V.; Baron, J. H. (Hammersmith Hosp., London W12 OHS, England). *Am. J. Gastroenterol.* 66(3):270-276; 1976.

Gastric (GA) and duodenal (DA) aspirates were analyzed in 20 control subjects and in 10 patients with duodenal ulcer, and the basal and maximum acid secretion (after pentagastrin stimulation) and the basal and near-maximum bicarbonate (BC) secretion (after secretin stimulation) were measured. In the basal secretion studies in controls, the volume of the DA was significantly greater than that of the GA, but there were no significant differences between the concentrations and outputs. In the patients, the volume of the DA was also significantly greater than that of the GA, but concentrations and outputs were significantly lower. There were no significant correlations between basal measurements of both aspirates in controls or patients. With respect to stimulated secretion, there were significant correlations between control gastric and duodenal volumes, but not between concentrations or outputs. The duodenal volumes and outputs were significantly higher than the gastric values. In the patients, there were significant correlations between gastric and duodenal volumes and outputs, but, again, not between concentrations. The outputs of gastric acid and duodenal BC in the patients were normal and almost identical (approximately 15-70 mEq/hr, mean 34.5). Under both basal and stimulated conditions, the patients secreted higher volumes of gastric juice, concentrations of acid, and acid outputs than controls. Although the volume of the basal DA was significantly higher in the patients, the BC concentration and output were only one-half that of the controls. This may be due to inadequate entry of BC into the duodenum, in spite of a normal BC secretory capacity.

1342 EXPERIENCE WITH SYNTHETIC SECRETIN IN THE TREATMENT OF DUODENAL ULCER.

(Eng.) Henn, R. M.; Selcon, S.; Sturdevant, R. A. L.; Isenberg, J. I.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Wilshire and Sawtelle Blvd., Los Angeles, CA 90073). *Am. J. Dig. Dis.* 21(11):921-925; 1976.

Thirteen hospitalized patients with endoscopically verified duodenal ulcer were studied to determine the effect of secretin on the clinical course of their disease. Seven patients received 333 μg of synthetic porcine secretin, s.c., every 4 hr for 10 days, and six patients received placebo injections on the same schedule. Repeat endoscopy was performed within 48 hr of completing the treatment period. The trial was discontinued because of transient, asymptomatic, hyperamylasemia in secretin-treated patients. Although significant gastric alkalinization could be reproducibly demonstrated in secretin-treated patients, secretin was not more effective than placebo in relieving pain or healing duodenal ulcer. Because the number of patients was small, however, definitive conclusions regarding efficacy of secretin in ulcer treatment could not be drawn.

1343 EFFECT OF PENTAGASTRIN ON TISSUE CULTURE OF GASTRIC AND DUODENAL MUCOSA ORIGINATING FROM PATIENTS WITH ULCER DISEASE.

(Pol.) Kleczkowska, A.; Kubien, E.; Wanicka, A.; Szafran, H.; Popiela, T. (Instytut Pediatrii AM, 30-663 Krakow, ul. Wielicka 265, Poland). *Pol. Tyg. Lek.* 30(50): 2081-2084; 1975.

The stimulating effect of pentagastrin (PG) on the culture of mucosal cells from the fundus and prepyloric region of the stomach and the duodenum, surgically removed from seven ulcer patients, is described. Cell cultures were grown routinely from the mucosa of all seven sections. Only the dishes whose bottoms were completely covered with multiplying cells were chosen for the study. They were divided into 2 groups, each containing 1 dish per patient. One group of culture cells received PG (0.5 μg/ml/day), the other group was given isotonic NaCl solution. The length of PG action on the cultures varied from 2 to 10 weeks, depending on the rate of complete coverage of the dish bottom. The fastest stimulation occurred in PG-treated cultures and controls from the duodenal mucosa; it was slower in the mucosa of the prepyloric area and slowest in treated and control cultures of the fundic region. The fact that PG-treated cell culture homogenates averaged 40% higher protein concentrations compared to controls was caused by a larger cellular mass. In one case, PG-treated fundic cells exhibited an epithelial composition of 56% versus 26.3% for NaCl solution and for fibroblasts, 33.7 versus 67.7%. Corresponding values for duodenal mucosa were 73.2 and 49.9%, resp., and for fibroblasts, 24.0 versus 47.2%. No clear-cut correlation between secretory capability of gastric mucosa and *in vitro* proliferation of fundic and prepyloric mucosa could be shown; it could, however, exist *in vivo*.

1344 LIPID ISLANDS IN THE GASTRIC MUCOSA AFTER RESECTION FOR BENIGN ULCER DISEASE.

(Eng.) Domellof, L.; Eriksson, S.; Helander, H. F.; Janunger, K. G. (Univ. Hosp., Univ. Umea, S-901 Umea, Sweden). *Gastroenterology* 72(1):14-18; 1977.

The prevalence of lipid islands after Billroth I and Billroth II resection was determined as a function of time in 316 patients, as well as in 286 as nonoperated controls. Gastroscopy and multiple biopsies were performed at selected intervals after surgery. The occurrence of single or multiple lipid islands increased with the postoperative time, independent of the original ulcer disease or the type of operation performed. In nonoperated patients, lipid islands were found in 6.3%, and approximately the same prevalence was found 1-3 yr after gastric surgery in Billroth II-operated patients. In both patient groups, a much higher prevalence was found 10-15 yr postoperatively, and 23 yr after Billroth II resection, 60% of the patients demonstrated lipid islands. At repeated gastroscopic examinations over a period of 1-2 yr, no certain changes in number, size, or distribution of the lipid islands were seen. The etiology of lipid islands is unknown, but intestinal-gastric reflux is the most plausible etiological factor.

SMALL INTESTINE

1351 PRIMARY INTESTINAL LYMPHOMA OF "WESTERN" AND "MEDITERRANEAN" TYPE, ALPHA CHAIN DISEASE AND MASSIVE PLASMA CELL INFILTRATION: A COMPARATIVE STUDY OF 37 CASES. (Eng.) Lewin, K. J.; Kahn, L. B.; Novis, B. H. (Center Health Sciences, UCLA, Los Angeles, CA 90024). *Cancer* 38(6):2511-2528; 1976.

The clinical and pathological features of 17 "Western" type primary abdominal lymphomas (WTL) were compared with those of 14 "Mediterranean" type (MTL) lymphomas. The MTL's involved only young adult Mulatto and African patients in whom malabsorption and abdominal pain were the major clinical features. The WTL's also predominantly affected Mulatto patients, but four cases occurred in Caucasians, and the mean age at presentation was 20 yr later. An obstructive presentation was the most common; only one patient in this group had evidence of malabsorption. The WTL's were located mainly in the distal small bowel and were nearly all of the monomorphic lymphocytic or histiocytic type. The MTL's occurred mainly in the duodenum and jejunum. In the MTL's, a spectrum of cells, ranging from those resembling atypical lymphocytes to large histiocytic types, was seen, some of the latter resembling Reed-Sternberg cells. The pattern of mesenteric node infiltration in the MTL's was also unusual in that preservation of the medullary sinuses was a common finding. In the MTL's, a heavy infiltration of mature-looking plasma cells associated with a fairly severe villous atrophy in the lamina propria of the small bowel was present. In the WTL's, the adjacent small bowel did not show this feature. In addition to the above cases, three patients with a similar heavy plasma cell infiltrate and villous atrophy, but without evidence of a lymphoma, are described. These cases may represent examples of MTL in a premalignant phase. Also included in this study are three patients with alpha-chain disease (α-CD), all with a heavy plasma cell infiltration and villous atrophy of the lamina propria, a pleomorphic type lymphoma involving the mesenteric nodes in all, and the small bowel in two was seen. Both genetic and environmental factors may be operative in the MTL's including the cases of α-CD.

1378 COELIAC DISEASE AND DERMATITIS HERPETIFORMIS: FURTHER STUDIES OF THEIR RELATIONSHIP. (Eng.) Scott, B. B.; Young, S.; Rajah, S. M.; Marks, J.; Losowsky, M. S. (St. James' Hosp., Leeds, England). *Gut* 17(10):759-762; 1976.

The incidences of celiac disease and of histocompatibility antigen HL-A8 were determined in 48 patients with dermatitis herpetiformis (DH), and the separate incidences of HL-A8 in DH patients with and without evidence of celiac disease were investigated. The diagnosis of DH was established by both the presence of a typical rash and of papillary IgA in clinically uninvolved skin by direct immunofluorescence. Nineteen percent of the DH patients had no evidence of celiac disease. The incidence of HL-A8 in the DH patients was 78%, which is considerably greater than that in healthy controls and no different from that reported in celiac disease. Furthermore, the incidence of HL-A8 was equally increased in those DH patients without evidence of celiac disease, suggesting that HL-A8 is associated with DH, regardless of its association with celiac disease.

LARGE INTESTINE

1389 CHANGES IN FECAL COMPOSITION AND COLONIC FUNCTION DUE TO CEREAL FIBER. (Eng.) Cummings, J. H.; Hill, M. J.; Jenkins, D. J. A.; Pearson, J. R.; Wiggins, H. S. (Dunn Nutrition Unit, Milton Rd., Cambridge, England). *Am. J. Clin. Nutr.* 29(12):1468-1473; 1976.

The effect on colonic function of adding wheat fiber to the metabolically-controled diets of six healthy volunteers for 3 weeks was studied. Increasing dietary fiber intake from 17 to 45 g/day increased fecal weight from 79 ± 6.6 g/day to 228 ± 29.9 g/day and shortened mean transit time, measured by a continuous marker method, from 57.8 ± 8.3 hr to 40.3 ± 8.9 hr. The increase in fecal weight was largely due to water. Fiber caused a dilution of fecal marker and an increase in fecal fat, nitrogen, and calcium output. Fecal sodium, potassium, and chloride showed only small changes, but volatile fatty acid output increased significantly without concentrations changing. Fecal bile acid output increased from 199 ± 46 mg/day to 279 ± 46 mg/day. This study shows that dietary wheat fiber affects colonic function in ways that might be important in protecting individuals against colonic cancer.

1390 ARTERIOVENOUS MALFORMATION IN CHRONIC GASTROINTESTINAL BLEEDING.

(Eng.) Cavett, C. M.; Selby, J. H., Jr.; Hamilton, J. L.; Williamson, J. W. (Univ. Mississippi Medical Center, 2500 N. State St., Jackson, MS 39216). *Ann. Surg.* 185(1):116-121; 1977.

Two cases of arteriovenous malformation (an 18-yr-old woman and a 61-yr-old man) are presented, and 47 other reported cases are reviewed. In both cases, barium contrast studies and endoscopy failed to demonstrate the lesion; this is also true in all previous cases. The diagnosis was made in both patients by selective mesenteric arteriography, which demonstrated a characteristic vascular tuft and very early venous phase. Forty-five percent of the previously reported cases were found in the cecum; 37 (80%) involved the distal ileum, cecum, ascending colon, or hepatic flexure. Seventy-five percent of all patients fall into the 50- to 80-yr age range. The literature reveals a recurring pattern of chronic gastrointestinal blood loss, anemia, and delay (even negative abdominal explorations) before the diagnosis is finally made. A more aggressive approach to chronic gastrointestinal bleeding through the use of selective mesenteric arteriography is suggested.

1391 PATHOGENESIS OF MASSIVELY BLEEDING COLONIC DIVERTICULOSIS: NEW OBSERVATIONS.

(Eng.) Meyers, M. A.; Alonso, D. R.; Baer, J. W. (New York Hosp.-Cornell Medical Center, New York, NY 10021). *Am. J. Roentgenol.* 127(6):901-908; 1976.

The site of bleeding, etiology, and pathogenesis in 10 cases of massively bleeding colonic diverticulosis were studied. Arteriographic, microangiographic, and detailed histologic observations demonstrated strikingly consistent changes related to the characteristic angioarchitecture of colonic diverticula. These changes included: asymmetric rupture of the vas rectum toward the lumen of the diverticulum precisely at its dome or its antimesenteric margin; conspicuous eccentric intimal thickening of the vas rectum, often with thinning of the media and duplication of the internal elastic lamina at and near the bleeding point; and general absence of diverticulitis. Comparison with control colonic diverticula suggested that traumatic factors arising within the diverticular or colonic lumen induce asymmetric intimal proliferation and segmental weakening of the associated vas rectum, predisposing to rupture and massive bleeding.

1392 FECAL CHARACTERISTICS CONTRASTED IN THE IRRITABLE BOWEL SYNDROME AND DIVERTICULAR DISEASE.

(Eng.) Goy, J. A. E.; Eastwood, M. A.; Mitchell, W. D.; Pritchard, J. L.; Smith, A. N. (Western General Hosp., Edinburgh, Scotland). *Am. J. Clin. Nutr.* 29(12):1480-1484; 1976.

The fecal characteristics of 11 healthy men, 14 patients with uncomplicated diverticular disease, 7 patients with spastic colon, and 17 patients with idiopathic diarrhea were compared. During a 3- to 5-day stool collection, no significant differences in fecal wet weight, dry weight, or total bile acid excretion were detected in the four groups. The water content of the stools of patients with idiopathic diarrhea was significantly greater than that of the stools of controls (79.8% versus 73.6%, $p<0.05$). Significantly less magnesium, potassium, and calcium was found in the stools of patients with diverticular disease than in those of controls ($p<0.0025$, $p<0.01$, and $p<0.05$, resp.), and a similar trend was noted in patients with spastic colon. These changes did not relate to the age of the patients, suggesting a common etiology for these disorders. The presence of increased water and primary bile acids in the feces of patients with idiopathic diarrhea suggests that this is a separate entity.

1393 PHASE III COMPARISON OF THE TREATMENT OF ADVANCED GASTROINTESTINAL CANCER WITH BOLUS WEEKLY 5-FU VS. METHYL-CCNU PLUS BOLUS WEEKLY 5-FU: A SOUTHWEST ONCOLOGY GROUP STUDY.

(Eng.) Baker, L. H.; Talley, R. W.; Matter, R.; Lehane, D. E.; Ruffner, B. W.; Jones, S. E.; Morrison, F. S.; *et al.* (Grace Hosp., 4160 John R. St., Detroit, MI 48201). *Cancer* 39(1):1-7; 1976.

The efficacy of a weekly bolus injection of 5-fluorouracil (5-FU; 400 mg/m^2, i.v.) or 5-FU (400 mg/m^2, i.v.) plus 1-2-chloroethyl-3-4-methyl 4-cyclohexyl 1-nitrosourea (methyl-CCNU; 175 mg/m^2, p.o., every 6 weeks) in the treatment of advanced gastrointestinal cancer was investigated in a randomized and stratified study of 294 patients. There was a highly significant partial remission rate for patients receiving the combination treatment ($p<0.01$). Nearly all patients receiving methyl-CCNU experienced nausea and vomiting; in the group receiving 5-FU alone, only 32% of the patients had gastrointestinal (GI) toxicity. A total of nine patient characteristics were examined for their relation to response and survival. The most important were (in order): sex, time from initial diagnosis to treatment, and performance status. These results confirm those of a previously published study. In the treatment of gastrointestinal cancer, a superior response rate may be attained with the combination of 5-FU and methyl-CCNU, in comparison with that attained with 5-FU alone. In colorectal cancer, the response rate with 5-FU was 9.5%, while the two drug treatment produced a response of 31.8% ($p=0.009$). The response in all gastrointestinal cancers to 5-FU was 10.6%, compared with 29.3% for the combination ($p=0.012$).

1394 SIMULTANEOUS TRANSITION OF MULTIPLE POLYPS INTO CARCINOMA IN THE LARGE INTESTINE. (Eng.) Kozuka, S.; Taki, T.; Kubota, K.; Yokoyama, Y. (Nagoya Univ. Sch. Medicine, 65 Tsurumacho, Showaku, Nagoya, 466, Japan). *Dis. Colon Rectum* 19(8):655-659; 1976.

Reports of surgical biopsy specimens from 41 patients with multiple epithelial neoplasms of the large intestine were evaluated. Sixteen patients had multiple polyps; 12 had a carcinoma, as well as one or more polyps; and 13 had two or more carcinomas. The number of polyps and carcinomas in each patient ranged from two to six. Distances between the neoplasms varied, but multiple polyps were usually found in groups within a single segment of the large intestine. Histologic specimens of the polyps were assigned to five grades according to the extent of epithelial pseudostratification in the glands. In every patient, the grades of histologic atypia among the multiple neoplasms were the same or only minimally different. Therefore, these lesions were considered to have arisen simultaneously or successively within a relatively short period. Of the 25 patients who had carcinoma *in situ* or infiltrating carcinoma, 17 had accompanying precancerous lesions or carcinoma elsewhere in the large intestine, and 8 had accompanying nonmalignant polyps. Areas of frankly infiltrating carcinoma frequently contained residues of adenomatous lesions, which suggested that the carcinomas had arisen from adenomatous polyps.

1395 FECAL STEROIDS IN POLYPOSIS COLI AND ILEORECTOSTOMY PATIENTS. (Eng.) Watne, A. L.; Core, S. K. (Charleston Foundation, West Virginia Univ., Morgantown, WV 26506). *J. Surg. Res.* 19(3):157-161; 1975.

Fecal bile acids and neutral steroids were examined in familial polyposis patients before and after surgery to determine whether abnormal fecal steroid levels act as carcinogens or as stimulants in the etiology of colon polyps. Fecal samples were collected from seven controls, seven patients with untreated Gardner's syndrome and/or familial polyposis, and five patients surgically treated for Gardner's syndrome by a subtotal colectomy with ileorectostomy. The cholic, chenodeoxycholic, lithocholic, deoxycholic, and hyodeoxycholic acid levels were determined in fecal samples. There was no significant difference in the total bile acids excreted between the three patient groups. The mean fecal excretions of cholic acid and chenodeoxycholic acid were 1.8 ± 1.7 and 1.6 ± 1.1 mg/g in the ileorectostomy group. The excretion of cholic acid at 0.6 ± 0.8 mg/g and chenodeoxycholic acid at 1.0 ± 0.8 mg/g in the polyposis group was significantly higher than in controls, who gave values of 0.06 ± 0.15 and 0.1 ± 0.3 mg/g, resp. There was no coprostanol in the fecal samples of the ileorectostomy group; means of 9.0 ± 8.0 mg/g and 18.0 ± 10.0 mg/g were found in the polyposis and control groups, resp. The cholesterol level for the ileorectostomy group was 17 ± 5 mg/g, compared with values of 12.0 ± 7.0 and 5.0 ± 4.0 mg/g for the polyposis and control groups, resp., indicating a lack of microbial action on cholesterol in the treated patients. Lithocholic and deoxycholic acid levels dropped from 3.6 ± 1.7 and 3.5 ± 1.6 mg/g, resp., in controls to 1.1 ± 0.8 and 1.0 ± 0.9 mg/g in the ileorectostomy group, with the polyposis group giving intermediate values of 2.4 ± 0.9 and 2.4 ± 0.7 mg/g, resp. The cholesterol level may influence cell permeability within the colon, thus increasing the susceptibility to carcinogenic agents. The change in fecal steroid pattern in patients with Gardner's syndrome indicates a higher risk to colon-related carcinogenesis.

PANCREAS

1439 ENDOSCOPIC PANCREATOGRAPHY IN EVALUATING RESULTS OF PANCREATICO-JEJUNOSTOMY. (Eng.) Kugelberg, C.; Wehlin, L.; Arnesjo, B.; Tylen, U. (Lasarettet, Fach, S-261 20 Landskrona, Sweden). *Gut* 17(4):267-272; 1976.

Postoperative results of two different types of pancreaticojejunostomy in 13 patients were evaluated with endoscopic retrograde cholangiopancreatography (ERCP). In four patients with longitudinal split of the pancreatic duct, two cases exhibited progress of the ductal inflammatory changes (further dilatation, irregularity, and formation of intraluminal concretions). Shunt patency was evident in all four cases on postoperative ductography. Among nine patients in whom caudal pancreaticojejunostomy was performed, definite signs of progress of inflammatory ductal changes were noted in six cases. Shunt patency, as evidenced by the passage of contrast medium, was obvious in one case and uncertain in one. All patients reported clinical improvement after surgery. It is concluded that pancreaticojejunostomy for chronic or acute relapsing pancreatitis is not a curative measure, but it may be regarded as palliative surgical intervention.

1440 CARCINOEMBRYONIC ANTIGEN (CEA) ACTIVITY IN PANCREATIC JUICE OF PATIENTS WITH PANCREATIC CARCINOMA AND PANCREATITIS. (Eng.) Sharma, M. P.; Gregg, J. A.; Loewenstein, M. S.; McCabe, R. P.; Zamcheck, N. (Deaconess Hosp., Boston, MA). *Cancer* 38(6):2457-2461; 1976.

The levels of carcinoembryonic antigen (CEA) activity in plasma and in pure pancreatic juice from 8 patients with carcinoma of the pancreas and 28 patients with pancreatitis were compared with those from 13 controls with no demonstrable pancreatic disease. Juice specimens were obtained via direct transduodenal cannulation of the pancreatic duct. The mean pancreatic juice CEA activities in controls, pancreatitis, and pancreatic carcinoma patients were 8.1 ng/ml, 18.6 ng/ml, and 309 ng/ml, resp. Pancreatic juice CEA activity in patients with cancer of the pancreas was significantly higher than in those with pancreatitis or in controls. None of the 32 patients with both pancreatic juice CEA activity less than 30 ng/ml and plasma CEA less than 2.5 ng/ml had pancreatic cancer; 3 of the 4 patients with CEA elevations in both fluids above these levels did have cancer. These findings suggest that combined measurement of CEA activity in plasma and pancreatic juice may help in diagnosing pancreatic disease.

1441 INTESTINAL ABSORPTION OF VITAMIN B_{12} IN PATIENTS WITH CHRONIC PANCREATIC INSUFFICIENCY AND THE EFFECT OF HUMAN DUODENAL JUICE ON THE INTESTINAL UPTAKE OF VITAMIN B_{12}. (Eng.) von der Lippe, G.; Andersen, K. J.; Schjonsby, H. (N-5016 Haukeland sykehus, Bergen, Norway). *Scand. J. Gastroenterol.* 11(7):689-695; 1976.

Studies were carried out to determine whether the reduced vitamin B_{12} absorption observed in patients with chronic pancreatic insufficiency is due to an effect of duodenal juice on the intestinal uptake of intrinsic-factor-bound vitamin B_{12} and to determine whether the absorption of vitamin B_{12} is related to the pancreatic secretion of bicarbonate. The mean absorption of vitamin B_{12} (Schilling test) was 13.1 ± 1.0% in 21 patients with chronic pancreatic insufficiency and 17.6 ± 1.4% in 13 control patients ($p<0.01$). There was no correlation between pancreatic bicarbonate production after secretin stimulation and vitamin B_{12} absorption in the patient group ($r=0.117$). Human duodenal juice reduced the uptake of $^{57}CoB_{12}$-rat intrinsic factor (IF) by perfused rat small intestinal segments *in vivo* ($p<0.01$), as well as the uptake of $^{57}Co_{12}$-human IF by purified guinea pig intestinal brush borders *in vitro* ($p<0.01$). The results confirm reduced absorption of vitamin B_{12} in chronic pancreatic insufficiency, but the mechanism remains uncertain.

PANCREAS

Pancreatitis

1445 EXPERIMENTAL MODEL OF PANCREATITIS IN DOGS. (Spa.) Pardo, H. A.; Servetti, E.; Cartazzo, J. M.; Noguera, G.; Bonaba, R. (Departamento de Cirugia, Facultad de Medicina, Av. Gral. Flores 2125, Montevido, Uruguay). *Cir. Urug.* 45(2):174-176; 1975.

A simple procedure for producing acute pancreatitis in dogs is presented. An injection of bile (4-6 cm^3) into the unligated pancreatic duct of 10 anesthetized dogs, produced experimental pancreatitis, as indicated by clinical, laboratory, and anatomopathological observations. Preoperative and postoperative amylase levels were 16-64 U and 128-256 U, resp. All of the dogs died within 12-90 hr. Necropsy revealed pancreatic cytosteatonecrosis, peritoneal serohemorrhagic exudate with digestive or hepatic congestion, and edematous pancreatitis with prenecrotic and necrotic sites. As there was no ligation, this technique lends itself to the evaluation of different therapeutic procedures.

1446 ACUTE PANCREATITIS: ANALYSIS OF FACTORS INFLUENCING SURVIVAL. (Eng.) Jacobs, M. L.; Daggett, W. M.; Civetta, J. M.; Vasu, M. A.; Lawson, D. W.; Warshaw, A. L.; *et al.* (Massachusetts General Hosp., Fruit St., Boston, MA 02114). *Ann. Surg.* 185(1):43-51; 1977.

To identify factors that distinguish patients with acute pancreatitis (AP) who can be expected to respond poorly to conservative measures from the entire patient population, a retrospective analysis of 519 cases of AP occurring over a 5-yr period was undertaken. Thirty-one percent of these patients had a history of alcoholism, and 47% had a history of biliary disease. The overall mortality was 12.9%. Of the symptoms recorded at the time of admission, hypotension, tachycardia, fever, abdominal mass, and abnormal examination of the lung fields correlated positively with increased mortality. Seven features of the initial laboratory examination correlated with increased mortality. Shock, massive colloid requirement, hypocalcemia, renal failure, and respiratory failure requiring endotracheal intubation were complications associated with the poorest prognosis. Among patients in this series with three or more of these clinical characteristics, maximal nonoperative treatment yielded a survival rate of 29%, compared to the 64% survival rate for a group of patients treated operatively with cholecystostomy, gastrostomy, feeding jejunostomy, and sump drainage of the lesser sac and retroperitoneum. High risk patients may benefit from early surgical intervention.

1447 ACUTE PANCREATIC PSEUDOCYSTS: INCIDENCE AND IMPLICATIONS. (Eng.) Bradley, E. L., III; Gonzalez, A. C.; Clements, J. L., Jr. (Emory Univ. Sch. Medicine, 69 Butler St., Atlanta, GA 30303). *Ann. Surg.* 184(6):734-737; 1976.

Attempts were made to define an acute pseudocyst, and to gain further information on the diagnosis and management of this entity. Of 92 patients with moderately severe acute pancreatitis initially studied within 3 weeks of onset by ultrasonic tomography, 52 developed an acute fluid collection in the lesser sac. Documentation of the ultrasound prediction of pseudocyst was achieved by surgery or autopsy in 26 cases. Spontaneous resolution of the acute pseudocyst was demonstrated by serial ultrasonography and radiography in another 10 patients. Exploration exposed three false-positive predictions of pseudocyst. Eleven other patients with a cystic configuration either refused surgery or were lost to follow-up. Acute pseudocyst formation is a relatively common phenomenon in the early phases of moderately severe pancreatitis. While spontaneous resolution of acute pseudocysts is frequent, in approximately 50% of cases, acute pseudocysts progress to chronic pseudocysts. A distinction between acute and chronic pseudocyst is necessary, since specific surgical management depends upon the phase of pseudocyst development. Unless regional sepsis supervenes, acute pseudocyst of less than 3 weeks' duration may be followed by serial ultrasonography in the hope of spontaneous resolution. When a pseudocyst has achieved chronic status, spontaneous resolution is rare. Persistent conservative management under these conditions invites the excessive mortality and morbidity of spontaneous rupture.

1448 ACUTE RENAL FAILURE IN PATIENTS WITH ACUTE PANCREATITIS. (Eng.) Goldstein, D. A.; Llach, F.; Massry, S. G. (Los Angeles County-

Univ. Southern California Medical Center, Los Angeles, CA). *Arch. Intern. Med.* 136(12): 1363-1365; 1976.

The cases of five patients with acute pancreatitis in whom acute renal failure developed in the absence of hypotension are described. Pancreatitis was diagnosed clinically, with mean serum and urinary amylase levels of 766 ± 197 and 2,378 ± 572 U/100 ml, resp. Acute renal failure developed within 24 hr after admission in all patients. It was manifested by oliguria, elevated levels of serum creatinine (6.9 ± 1.1 mg/100 ml) and blood urea nitrogen (105 ± 28 mg/100 ml); a urinary sodium level of 72.0 ± 6.6 mEq/l; and an isosmotic urine level of 355 ± 31 mOsm/l. The mean uric acid level was 18.6 ± 1.6 mg/100 ml. The lowest mean diastolic blood pressure was 96 ± 6 mm Hg. The duration of the oliguric phase of acute renal failure was 8.2 ± 1.7 days, and all patients recovered from both the acute pancreatitis and acute renal failure. Acute pancreatitis, *per se*, can precipitate acute renal failure. It occurs early in the course of the pancreatitis, and extreme hyperuricemia is a frequent finding that does not adversely affect the recovery of renal function.

1449 ACUTE PANCREATITIS IN SZCZECIN CLINICS AND HOSPITALS IN THE YEARS 1964-1974. EPIDEMIOLOGY, SYMPTOMATOLOGY AND CLINICAL PICTURE. (Pol.) Kopylow, A.; Majewska, M.; Synoradzka, K.; Kaczmarek, W.; Marlicz, K.; Zajac, J. (Klinika Chorob Wewnetrznych I.Ch.W. PAM, ul. Unii Lubelskiej 1, 71-344 Szczecin, Poland). *Przegl. LIVER AND BILIARY TRACT

1453 INFUSION HEPATIC ANGIOGRAPHY IN DIAGNOSIS OF LIVER METASTASES. (Eng.) Rosch, J.; Freeny, P.; Antonovic, R.; Gutierrez, O. H. (Univ. Oregon Health Science Center, 3181 Sam Jackson Park Road, Portland, OR 97201). *Cancer* 38(6): 2278-2286; 1976.

Experience with infusion hepatic angiography and with conventional angiography is presented, and the diagnostic effectiveness of the two techniques is compared. Infusion hepatic angiography was used, together with conventional angiography, diagnostically in 68 patients with liver metastases. The combination of both techniques led to a diagnostic accuracy of 97%. Metastases were missed in only two patients, both of whom had underlying liver or biliary disease. In a comparison of the two techniques, infusion angiography was diagnostically essential in 5 patients (7%) and afforded improved diagnosis in 49 others (72%). In 10 patients (15%), it gave equivalent information; and in 4 patients (6%), it provided less information than the conventional technique. Infusion hepatic angiography is a useful complementary technique in anatomic liver diagnosis, especially because of its ability to improve upon the diagnostic accuracy of the capillary phase of hepatic angiography.

1454 CORRELATION OF SCINTIGRAPHY WITH SHORT INTERVAL AUTOPSY IN MALIGNANT FOCAL LIVER DISEASE, A STUDY OF 59 CASES. (Eng.) Ruiter, D. J.; Byck, W.; Pauwels, E. K.; Taconis, W. K.; Spaander, P. J. (Pathologisch Laboratorium der Rijksuniversiteit, Boerhaavekwartier, Wassenaarseweg 62, Leiden, Netherlands). *Cancer* 39(1):172-177; 1977.

The accuracy of scintigraphy was evaluated by comparing scintigraphy and autopsy findings in 59 patients: 56 with malignant diseases (carcinoma, 44; sarcoma, 2; lymphoma, 8; other, 2) and 3 with nonmalignant diseases (duodenal ulcer, myelofibrosis with peliosis hepatitis, and rheumatoid arthritis with vasculitis and cachexia). Autopsy was performed within a few weeks of scintigraphy, and the number of focal lesions, percentage of liver affected, and weight of the liver and spleen were also compared. The overall accuracy of scintigraphy was 49/59 cases, with 4/26 false-positive and 6/33 false-negative reports. Five of the 10 cases with lesions ≤ 2.5 cm were missed, compared to 1/23 cases with a larger lesion ($p<0.03$). No lesion >4 cm was missed. Incorrect interpretation was almost always made in patients with a liver weighing <2,000 g (9/30); accuracy was much higher in 28/29 patients with heavier livers ($p<0.0025$). Detection of a single focal lesion by scintigraphy was unreliable (2/13). The correlation between the spleen weight calculated from the scintigram and that found at autopsy was poor, but the correlation between both liver weights was more satisfactory.

1455 EFFECTS OF EXPERIMENTAL HEPATIC ARTERY EMBOLIZATION ON HEPATIC FUNCTION. (Eng.)

Cho, K. J.; Reuter, S. R.; Schmidt, R. (Univ. Michigan Medical Center, Ann Arbor, MI 48109). *Am. J. Roentgenol.* 127(4):563-567; 1976.

The effect of embolization on hepatic function was evaluated in 12 dogs. Embolization of the hepatic artery was effected with Gelfoam. Liver function studies, including SGPT, alkaline phosphatase, BSP test, and bilirubin, were done serially over a 6-week period following the embolization. Eleven of the 12 dogs survived the 6-week period. Hepatic artery embolization caused some liver damage; however, recovery occurred by 6 weeks. These results suggest a possible therapeutic role for hepatic artery embolization in patients with massive hepatic bleeding or hemobilia who are not surgical candidates and who would require hepatic lobectomy or dearterialization to control the bleeding.

1456 SERUM BILE ACID CONCENTRATIONS IN PATIENTS WITH LIVER DISEASE. (Eng.)

Fausa, O.; Gjone, E. (Medical Dept. A, Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 11(5):537-543; 1976.

Fasting and 2-hr postprandial serum bile acid concentrations were determined in 49 patients with various liver diseases by an enzymatic-fluorimetric method, using a highly purified 3α-hydroxysteroid dehydrogenase. Twenty-two patients had cholestatic hepatobiliary diseases (CHD; extrahepatic occlusion, primary biliary cirrhosis, and biliary tract diseases in ulcerative colitis), and 21 patients had predominantly parenchymatous diseases (PD; chronic active hepatitis and liver cirrhosis). Fasting bile acid concentrations were elevated (≤ 7.5 mM) in all patients with serum bilirubin >1.0 mg/dl and in seven with normal bilirubin. In both patient groups, however, the levels correlated significantly to bilirubin ($p<0.001$ for CHD patients, $p<0.01$ for PD patients) and to SGOT ($p<0.05$), but not to SGPT, alkaline phosphatase, or albumin. Postprandial concentrations were above normal (≥ 10.0 μM) in all CHD patients with biochemical and/or histological signs of cholestatic disease, even if fasting concentrations were normal. In PD patients, postprandial concentrations correlated significantly with bilirubin ($p<0.01$) and with SGOT and SGPT ($p<0.02$), but not with alkaline phosphatase or albumin. Fasting and postprandial serum bile acid concentrations tended to be a more sensitive test of hepatobiliary disease than bilirubin and the transaminases in both patient groups.

1457 INVESTIGATIONS OF THE ACTIVITY OF ARYLSULPHATASE A AND B IN LIVER TISSUE AND SYSTEMATIC FLUIDS IN SELECTED DISEASES OF THE LIVER AND BILE DUCTS. (Pol.)

Wieczorek, E. (61-047 Poznan, ul. Warszawska 106, Poland). *Pol. Przegl. Chir.* 47(9):1081-1086; 1975.

A comparative study of the activity of arylsulfatase A and B in serum, liver, and urine as a diagnostic criterion in some liver and biliary tract diseases is presented. The patients (117) were divided into four groups: group 1 consisted of 52 patients with gallbladder stones; group 2 contained 20 patients with gallstone-induced jaundice; group 3 was composed of 12 patients with neoplasm-induced icterus; and group 4 had 17 controls without liver or biliary tract symptoms. Mean arylsulfatase A and B values in the liver, serum, and urine of the first three groups were higher than those in the control group. They were highest in the urine and blood serum of patients with neoplastic jaundice and extrahepatic cholelithiasis. Increased arylsulfatase A and B activity in serum coincided with higher alkaline phosphatase levels, along with other results indicating liver damage. It was also shown that arylsulfatase A and B ratio in liver tissue and blood serum was higher than 1 in all groups, except in neoplastic jaundice (0.89) and primary liver tumor (0.66). Determination of this ratio might be utilized for differentiation of benign and malignant types of jaundice.

1458 ICTERIC TYPE HEPATOMA. (Eng.)

Lin, T. Y; Chen, K. M.; Chen, Y. R.; Lin, W. S. J.; Wang, T. H.; Sung, J. L. (Natl. Taiwan Univ. Hosp., Taipei, Taiwan, R.O.C.). *Med. Chir. Dig.* 4(5/6):267-270; 1975.

Clinical and surgical findings in eight cases of icteric hepatoma are reported, and the case history of one of these patients is presented. All patients had a history of biliary stone-like attacks and jaundice. Because this tumor invades and ruptures the bile duct before it is discernable, the diagnosis was established only by histologic examination of an evacuated blood clot or necrotic tissue obtained from the bile duct at operation.

1459 SOME PARAMETERS OF SERUM ENZYME ACTIVITY IN PATIENTS WITH A MALIGNANT PROCESS OF THE LIVER. (Cro.)

Roguljic, A.; Kolaric, K.; Petrinovic, R. (Central Inst. Tumors and Similar Diseases, Zagreb, Yugoslavia). *Acta Med. Iugosl.* 29(2):177-184; 1975.

To test the value of serum enzyme activity in the early diagnosis of malignant processes in the liver, serum alkaline phosphatase, total and liver lactate dehydrogenase, GOT, GPT, and γ-glutamyltranspeptidase levels were studied in 10 men and 15 women with malignant processes in the liver (principally carcinoma) with different primary localizations. The malignant process was cytopathohistologically verified in all patients. γ-Glutamyltranspeptidase, liver lactate dehydro-

enase, and alkaline phosphatase levels were
ignificantly elevated, giving a positive
iagnosis in 100%, 96%, and 84% of the studied
atients, resp. ^{198}Au-scintigraphy of the liver,
owever, showed a positive diagnosis in only 67%
f the patients examined. Serum levels of certain
nzymes can thus be valuable in diagnosing malignant
rocesses in the liver, but since elevated enzyme
evels may also accompany other liver diseases,
omparative data should be collected.

460 TREATMENT OF SYMPTOMATIC HEPATIC CYST BY PERCUTANEOUS INSTILLATION OF PANTO-
QUE. (Eng.) Goldstein, H. M.; Carlyle, D. R.;
lson, R. S. (M. D. Anderson Hosp. and Tumor
st., Houston, TX 77030). *Am. J. Roentgenol.*
7(5):850-853; 1976.

e case of a 57-yr-old man in whom the percutaneous
stillation of isophendylate was used in the manage-
nt of a large, symptomatic, simple hepatic cyst
presented. The lesion was diagnosed by ^{99m}Tc
lfur colloid liver scan, hepatic arteriography,
trasonography, and puncture and radiography of
e cyst. In an attempt to sclerose the cyst,
ophendylate (9 ml) was injected. Subsequent
alysis of the cystic fluid revealed the presence
occult blood and a cholesterol level of 115 mg/100
, a bilirubin level of 2.5 mg/100 ml, and an LDH
vel of 715 mU/100 ml. Six months later, plain
diographs demonstrated evidence of a fibrous
action within the cyst, and the cyst was no longer
parent on ultrasonography. Sixteen months after
ncture, the patient remains asymptomatic, and the
diographs remain unchanged. These results suggest
at percutaneous instillation of sclerosing agents
y provide an alternative to operative procedures
the management of hepatic cyst.

61 PATHOLOGY OF LIVER TRANSPLANTATION. (Eng.) Roddy, H.; Putnam, C. W.; Fennell, R. H.,
. (Univ. Colorado Medical Sch., Denver, CO 80220).
nsplantation 22(6):625-630; 1976.

erience with 76 liver transplantations in 67
ients is reviewed in an attempt to ascertain
ses of failure and to aid in setting guidelines
better results. Previous experience with renal
nsplantation indicates failure of the graft is
ally due to immunological rejection; in the
sent sample, rejection was the primary cause of
ft failure in only 4 of the 64 cases in which
graft survived the first postoperative week.
two most common causes of transplant failure
e technical difficulties with the operative
cedure and sepsis; these accounted for 47 (62%)
ft failures in 76 transplants. Biliary obstruc-
n and sepsis are more common causes of liver
lure than rejection, and patients with recurrent
ndice are now studied intensively for evidence
obstruction. Only after obstruction is excluded
immunosuppression intensified. The future of
er transplantation in the management of potential-
fatal liver disease appears to be encouraging.

1462 CHRONIC INTRAHEPATIC CHOLESTASIS OF SARCOIDOSIS. (Eng.) Rudzki, C.; Ishak, K. G.; Zimmerman, H. J. (George Washington Univ. Sch. Medicine, Washington, DC). *Am. J. Med.* 59(3): 373-387; 1975.

The clinical, biochemical, immunologic, and histologic findings in five men with sarcoidosis and jaundice in whom a syndrome resembling primary biliary cirrhosis developed are described. The average age of the onset of symptoms was 27 yr. Results of the tuberculin test were negative in four of five cases. Hepatomegaly and splenomegaly were present in all. Failure of normal lymphocyte transformation by phytohemagglutinin was seen in one of the three tested, and another had a borderline response. Causes other than sarcoidosis for granulomatous disease could not be demonstrated. Insidious onset of pruritus and jaundice, and strikingly elevated levels of serum alkaline phosphatase, were seen in all five patients. Histologic features characteristic of primary biliary cirrhosis included a decrease in the number of portal bile ducts and increased amounts of copper in hepatocytes. Therapeutic efforts included glucocorticoids, chloroquine, and phenobarbital; the patients survived from 7 to 18 yr after onset. Portal hypertension was present in three patients. Clinical features of disseminated granulomatous disease consistent with sarcoidosis preceded or were prominent features of chronic intrahepatic cholestasis. The data indicate a diagnosis of sarcoidosis concomitant with chronic intrahepatic cholestasis.

1463 WILSON DISEASE. COMPARATIVE ULTRASTRUCTURE IN A SIBSHIP OF NINE. (Eng.) Lough, J.; Wiglesworth, F. W. (Montreal General Hosp., 1650 Cedar Ave., Montreal, Quebec, Canada). *Arch. Pathol. Lab. Med.* 100(12):659-663; 1976.

Comparative electron microscopy was carried out on liver tissue from nine siblings to determine whether presymptomatic, affected patients with Wilson's disease could be differentiated from heterozygous, normal carriers. Two of the nine developed the neurologic manifestations of the disease; three others were considered homozygous, but normal; two were heterozygous and normal; and two were classified as genotypically uncertain, because of borderline biochemical abnormalities. Alterations of the mitochondria and endoplasmic reticulum suggestive of copper toxicity were present in both the heterozygous and the genotypically uncertain siblings. Variation in size and shape of the mitochondria, dilation of smooth endoplasmic reticulum, and greatly enhanced autophagolysosomal activity, with digestion of mitochondria and accelerated production of lipofuscin-laden residual bodies, were seen. A clear distinction could not be made. The severity of the abnormalities appeared to correlate with liver copper level, and organelle changes preceded lipid accumulation.

Hyperbilirubinemic States

1505 ETHNIC DIFFERENCES IN NEONATAL JAUNDICE: COMPARISON OF JAPANESE AND CAUCASIAN NEWBORN INFANTS. (Eng.) Horiguchi, T.; Bauer, C. (Coll. Physicians and Surgeons, Columbia Univ., 630 W. 168th St., New York, NY 10032). *Am. J. Obstet. Gynecol.* 121(1):71-74; 1975.

A statistically significant increased incidence of neonatal jaundice among 75 Japanese infants born in New York, compared to 50 Caucasian infants born during the same period, is reported. The incidence in the Japanese infants was 57%, compared to 16% in the Caucasian group. The groups were comparable in terms of antenatal and intrapartum care, maternal age, parity, intrapartum medication, type of delivery, and anesthesia. Hyperbilirubinemia exceeding 15 mg% was observed in 23% of the Japanese infants and in none of the Caucasian group. Special attention to this type of jaundice in patients of Oriental origin by obstetricians and pediatricians is urged.

1506 CLINICAL EFFECTS OF MEDICATION ON CONSTITUTIONAL JAUNDICE: STUDIES ON THE EFFECT OF BUCOLOME ON GILBERT'S SYNDROME AND DUBIN-JOHNSON SYNDROME. (Jpn.) Yamamoto, T.; Kosaka, K.; Ichida, F.; Kanetaka, T.; Kameda, H.; Namihisa, T.; *et al.* (Kliniki Univ. Sch. Medicine, Japan). *Jpn. Arch. Int. Med.* 21(12):427-437; 1974.

The effectiveness of bucolome in reducing serum bilirubin was studied in 30 cases of Gilbert's syndrome and 15 cases of Dubin-Johnson syndrome. Bucolome (300-mg capsules) was administered p.o. three times a day for 4 weeks. Medication levels were increased to 1,200 or 1,800 mg/day in 11 cases. Serum bilirubin levels were measured continuously from one month before administration of the drug to one month after its discontinuation. In 21/30 cases of Gilbert's syndrome, serum bilirubin concentration decreased by more than 1.5 mg/dl, or by more than 50% of the original level. In the remaining 9 cases, 7 showed decrease in the range of 0.5-1.4 mg/dl, and 2 cases decreased by less than 0.4 mg/dl. No increases in serum bilirubin occurred during administration of bucolome. Ameliorating effects on jaundice were evident in 21/30 cases, from external observation. Out of 22 patients followed after discontinuation of the drug, serum bilirubin returned to pretreatment levels after several weeks in 11 cases. In 4/15 cases of Dubin-Johnson syndrome, maximum serum bilirubin decreases of 18-35% occurred, but results were unclear. Bucolome seemed ineffective in Dubin-Johnson syndrome. Side effects, all of which disappeared after discontinuation of the drug, included gastrointestinal disorders (7), rash (1), itching (1), and speech and sight impairment (1)

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

1509 TUBERCULOUS PSEUDOTUMORS OF THE LIVER. (Eng.) Zipser, R. D.; Rau, J. E.; Ricketts, R. R.; Bevans, L. C. (Los Angeles County—Univ. Southern California Medical Center, 1200 N. State St., Los Angeles, CA 90033). *Am. J. Med.* 61(6): 946-951; 1976.

A rare case of tuberculous pseudotumors of the liver occurred in a 35-yr-old man who presented with a 6-week history of daily fever, night sweats, malaise, and a 20-pound weight loss and with a 5-month history of adenopathy in the neck. Results of liver function studies were nonspecific and common to most space-occupying lesions: transaminase and bilirubin levels were normal, alkaline phosphatase was moderately increased, albumin decreased, globulin increased, and prothrombin time was slightly prolonged. Liver scan disclosed numerous filling defects in the liver, with a mild increased bone marrow uptake. Therapy with isoniazid and ethambutol was begun, with no real improvement, and a laparotomy was performed. The liver surface contained multiple nodules, varying in diameter from 2 mm to 5 cm; numerous firm para-aortic nodes approximately 2 cm in diameter and a firm mass in the head of the pancreas were also found. The initial impression was metastatic carcinoma, possibly of pancreatic origin. However, on the fourth postoperative day, acid-fast stains confirmed the presence of tuberculous bacilli in the liver tissue, and rifampin was added to the antibiotic regimen. The response to antituberculous drug therapy was rapid. *Mycobacterium tuberculosis* was identified 2 weeks later from liver tissue culture. Unusual presentations of metastatic carcinoma to the liver should be thoroughly investigated with pathologic and bacteriologic studies, and tuberculous pseudotumors should be considered.

1510 LIVER FUNCTION TESTS FOLLOWING ANAESTHESIA. (Eng.) McEwan, J. (Queen Alexandra Military Hosp., Millbank, London, England). *Br. J. Anaesth.* 48(11):1065-1070; 1976.

The effects of halothane and nonhalothane anesthetics on liver function were compared in 41 men undergoing repeated transurethral surgery. All subjects had received multiple halothane anesthetics in the past. On the first occasion, the anesthetic consisted of a sleep dose of thiopentone, followed by 66% nitrous oxide in O_2 and 1%-1.5% halothane reduced to 0.5%-1% by a mask, using a Mapleson A circuit. The nonhalothane anesthetic consisted of thiopentone followed by 80 mg gallamine and ventilation with nitrous oxide (7.5 l/min) and O_2 (2.5 l/min) using an East Autovent nonrebreathing circuit. In both procedures, premedication was with papaveretum and hyoscine. Blood samples were taken before anesthesia and after operation. There was a smaller disturbance of liver function after halothane than after nonhalothane anesthesia. In general, however, alkaline phosphatase values in all patients except one were unchanged. Pyrexia and eosinophilia were absent after operation; no patient was positive for hepatitis B surface antigen, antibody, or antigen-antibody complex. SGOT and SGPT levels were increased more often ($p = 0.05$) after the nonhalothane anesthetic. Increased bilirubin values and altered albumin/globulin ratios occurred in three patients after nonhalothane anesthesia. There was no obvious correlation between altered liver function tests and the number of anesthetics or the total duration of anesthesia. When patients have had more than four previous halothane anesthetics, it may be less upsetting to liver function to continue to use halothane thereafter.

Acute Viral Hepatitis

1512 RADIOHEPATOGRAPHY WITH ^{125}I-ROSE BENGAL IN PATIENTS WITH VIRUS HEPATITIS AND WITH IDIOPATHIC JAUNDICE OF PREGNANCY. (Pol.) Czarnecki, L.; Golba, S.; Neumann, H. (Instytut Chorob Wewnetrznych Sl., ul. Roosevelta 49, 41-902 Bytom, Poland). *Pol. Przegl. Radiol.* 39(5):599-602; 1975.

A comparison of the effectiveness of radiohepatography with ^{125}I-rose bengal (CBI 125) and some liver function tests in viral hepatitis and idiopathic jaundice of pregnancy is reviewed. A group of 79 patients was divided into: group 1, 30 patients without findings of hepatopathy; group 2, 41 patients with viral hepatitis; and group 3, 8 women with idiopathic jaundice of pregnancy. The radioisotope was administered i.v. at 0.2 μCi/kg body weight. All subjects participating in the study received 3 x 15 drops of Lugol's Fluid on the day preceding and 2 days after the isotope injection. Group 2 was examined twice with the radioisotope--at the onset of the disease and at the time of the recession of the clinical symptoms and normalization of biochemical tests performed for all groups. These tests included determination of alanine and asparagine aminotransferases, bilirubin level, iron test, and the γ-globulin level. The capacity of the liver to secrete dye (Te), its capacity to remove dye from the blood (Tu), and the percent of dye in the hepatic blood (R) were determined. It was found that in group 2, Tu lasted nearly twice as long as in group 1 during the first examination, while R amounted to 40 ± 15.6 and 16 ± 3.2, resp. The second test in group 2 during convalescence showed return to standard Tu and R values. In group 3, Tu and R were 42 and 78, resp., which was attributable to intrahepatic cholestasis. Te in groups 2 and 3 indicated considerable liver damage. During viral hepatitis, the radioisotope test proved to be as sensitive and simple as biochemical function tests, but was not useful in the differentiation of viral hepatitis and idiopathic jaundice of pregnancy.

1513 THE STUDY OF HEPATIC STRUCTURE IN VIRAL HEPATITIS. (Eng.) Schaffner, F. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Rush-Presbyt. St. Luke's Med. Bull.* 15(2):123-131; 1976.

Changes in hepatic structure associated with viral hepatitis are reviewed. In acute hepatitis, single hepatocytes or small groups of hepatocytes undergo liquefaction necrosis, which elicits a focal inflammatory response and portal inflammation. Occasiona hepatocytes undergo coagulation necrosis. Electron microscopy reveals that acidophilic "Councilmanlike bodies are dead hepatocytes. Protracted acute lobular hepatitis may progress to more serious chronic disease. Nonspecific structural abnormalities, which include small histocytic nodules, foca necrosis, and portal inflammation, persist as the acute lobular hepatitis heals, but before hepatic function tests return to normal. In chronic portal hepatitis, the inflammation which had extended from the portal tracts into the parenchyma during the acute stage retracts to within the portal tracts, allowing the limiting plates of hepatocytes to restore themselves. When the lobular component of acute hepatitis subsides but the portal and periportal inflammation does not, the resulting chronic periportal hepatitis is called aggressive. The los of hepatocytes in the limiting plate, with resultan inflammation and subsequent fibrosis, is piecemeal necrosis, the *sine qua non* of chronic active hepatitis. Hepatocytes containing hepatitis B surface antigen are larger than normal, because the bulky cytoplasm has a smudged appearance similar to groun or frosted glass. These cells are usually in small groups, with no zonal predilection. Hepatocytes from chimpanzees infected with hepatitis A show clumped endoplasmic reticulum and abnormal mitochondria. Also, large clumps of granules, which ar probably heterochromatin for virus A RNA synthesis, are observed at the peak of the disease. In contra to hepatitis B, the morphological changes seen in hepatitis A last only a week or two; normalcy is then restored.

1514 HISTOPATHOLOGY OF ACUTE AND CHRONIC HEPATITIS. (Eng.) Desmet, V. (Academisch Ziekenhuis Sint-Rafael, Katholieke Universiteit, Kapucijnenvoer 33, B-3000 Leuven, Belgium). *Acta Gastroenterol. Belg.* 39(9/10):299-306; 1976.

The histopathological characteristics of acute and chronic hepatitis are surveyed. In acute hepatitis pathological changes occur in the lobular parenchym and portal tracts. The lobular lesions consist of liver cell damage and necrosis, inflammatory cell filtration, development of macrophages, and cholest sis. One striking feature is liver cell pleomorph in which swelling of liver cells, formation of balloon cells, and acidophilic degeneration and format of acidophilic bodies occur. The extent of necros reflects the severity of the disease, and different egrees and patterns can be distinguished: single-ell, focal confluent, intra- and interlobular conluent, panlobular, and multilobular necrosis. Poral changes consist of inflammatory, mainly lymphoytic, infiltration. Chronic hepatitis encompasses broad spectrum of liver disease. It is imperative o distinguish, as far as possible, between chronic epatitis and cirrhosis, and laparoscopy has been elpful in establishing the latter diagnosis. Two ubgroups of chronic hepatitis are chronic persistent epatitis, characterized by portal lymphocytic iniltration, and chronic aggressive hepatitis, which s dominated by more severe portal and periportal nflammation. More active cases go through repeated pisodes of inter- or multilobular confluent parenhymal necrosis, and lesions of the portal bile ducts ay occur.

515 PASSIVE IMMUNIZATION AGAINST VIRAL HEPATITIS—STATUS AND PROSPECTS. (Eng.)
rady, G. F. (State Lab. Inst., 375 South St., oston, MA 02130). *Am. J. Med. Sci.* 270(2):369-74; 1975.

he role of γ-globulin in the development of passive mmunity to viral hepatitis is reviewed. Recent nformation suggests that the potency of anti-hepaitis A γ-globulin will remain high because of the arge blood donor population available. The present ecommended dose is 0.01 ml/lb. In high-risk roups, γ-globulin has been shown to be 80-84% ffective in suppressing hepatitis A. Globulin repared in the last 5 yr has yet to be tested in ommunity outbreaks. The recent identification f the A virus and the development of *in vitro* ests for homologous antibody may provide an adeuate predictive index of clinical effectiveness. nti-hepatitis B globulin prepared from volunteer lasma has shown a rising titer or antibody since 968 when urban epidemics were first noted. In ddition, titers have risen further, possibly ecause routine screening of blood donors has liminated carriers of hepatitis B surface antigen. n nonparenteral exposure to small amounts of noculin, conventional globulin was as effective as pecific, high-titer anti-hepatitis B antisera in ttenuating the infection and decreasing the number f carriers. Hyperimmune globulin has also been hown to be effective in attenuating infection. he prevention of hepatitis B in infants following aternal transmission of antigen is a suggested use or this serum. Prevention of hepatitis B due to ransfusion using donor globulin has met with little uccess. Conventional γ-globulin may be prophylactic n nonparenteral low-dose exposure to hepatitis B. pecific high-titer γ-globulin may be effective in eutralizing antigen from massive exposure.

516 PASSIVE IMMUNOTHERAPY IN HBsAg FULMINANT HEPATITIS: RESULTS ON ANTIGENAEMIA AND JRVIVAL. (Eng.) Gateau, P.; Opolon, P.; usinovici, V.; Ropars, C.; Caroli, J. (Gastroenterlogical Unit, CHU Saint-Antoine, 184, rue Fbg Saintntoine, F-75012 Paris, France). *Digestion* 14(4):)4-310; 1976.

The number of exchange transfusions and the amount of anti-hepatitis B surface antigen (anti-HBs) plasma required to obtain circulating hepatitis B surface antigen (HBsAg) disappearance were investigated. Nineteen patients with HBsAg-positive fulminant hepatitis underwent exchange transfusions and anti-HBs-rich plasma infusions. Circulating HBsAg disappeared in 17 cases: exchange transfusion alone or in combination with one dose of anti-HBs caused the disappearance of circulating HBsAg in 3 and 10 patients, resp. A second exchange transfusion was needed in three patients. The maximal circulating anti-HBs titer detected by radioimmunoassay was higher in the nine patients who showed evidence of liver generation than in the remaining patients (71 ± 24% versus 37 ± 24%). There was no correlation between circulating anti-HBs level and the amount of anti-HBs-rich plasma administered. Recovery was observed in 36% of the cases. As the beneficial effect of such treatment is not yet evident, a controlled trial of patients paired with respect to the number of exchange transfusions and amount of real or placebo anti-HBs should be conducted.

1517 LYMPHOCYTOTOXINS IN ACUTE AND CHRONIC HEPATITIS. CHARACTERIZATION AND RELATIONSHIP TO CHANGES IN CIRCULATING T LYMPHOCYTES. (Eng.)
Dehoratius, R. J.; Henderson, C.; Strickland, R. G. (Jefferson Medical Coll., Philadelphia, PA 19107). *Clin. Exp. Immunol.* 26(1):21-27; 1976.

The lymphocytotoxicity (LCT) in hepatitis serum was characterized, and the relation between LCT and T-cell depression in patients with acute hepatitis (AH) or chronic hepatitis (CH) was determined. Ninety patients were studied: 51 with AH; 29 with CH; and 10 who were asymptomatic carriers of hepatitis B surface antigen (HBsAg), but who had no previous history of icteric hepatitis. LCT against unfractionated lymphocyte target cells was found in 29/51 AH sera, in 21/29 CH sera, and in 0/10 carrier sera, suggesting that there is a relation between LCT and liver damage. LCT was active at physiological temperatures, but maximum cytotoxicity was observed at 15 and 37 C. Sera from AH and CH patients were reactive *in vitro* against cell surface determinants on both T and B cells. Serial determinations of peripheral blood T- and B-cell proportions and LCT were carried out in 21 AH and 14 CH patients. As T-cell proportions returned to normal, LCT decreased. There was a significant negative correlation between percentage change in T-cell levels and percentage change in LCT ($p<0.001$). LCT may be partly responsible for the T-cell depression in AH and CH. Although liver cell damage and/or persistent viral infection could account for the immunological abnormalities, it is suggested that liver damage *per se* is of greater importance.

1518 ENHANCED HBsAb PRODUCTION IN PATHOGENESIS OF FULMINANT VIRAL HEPATITIS TYPE B.
(Eng.) Woolf, I. L.; El Sheikh, N.; Cullens, H.; Lee, W. M.; Eddleston, A. L. W. F.; Williams, R.; Zuckerman, A. J. (King's Coll. Hosp., London SE5 8RX, England). *Br. Med. J.* 2(6037):669-671; 1976.

Sera from 17 patients with fulminant type B hepatitis were compared with those from 20 patients with severe but nonfulminant disease, to investigate the possible importance of humoral immunity in the pathogenesis of fulminant hepatitis. Hepatitis B surface antigen (HBsAg) was cleared from the serum significantly faster ($p<0.001$) in fulminant hepatitis patients. In 41%, anti-HBsAg (HBsAb) was detectable by radioimmunoassay (RIA) at presentation. In all 11 sera from patients with fulminant hepatitis examined by electron microscopy, aggregates of HBsAg and HBsAb were seen. In contrast, HBsAb was never detected by RIA in patients with nonfulminant hepatitis; aggregates were seen by electron microscopy in only one serum specimen (5%). A significant sex difference between fulminant and nonfulminant hepatitis was observed; 65% of the patients with fulminant hepatitis and 15% of the patients with nonfulminant hepatitis were women ($p<0.01$). Enhanced HBsAb production in fulminant hepatitis, by leading to free HBsAb in portal blood, may cause an Arthus reaction in the sinusoids of the liver, with ensuing ischemic necrosis of hepatocytes.

1519 DETECTION OF HEPATITIS B SURFACE ANTIGEN BY MEANS OF ORCEIN STAINING OF LIVER.

(Eng.) Kostich, N. D.; Ingham, C. D. (Clinical Lab., Chicago Ave. at 27th St., Minneapolis, MN 55407). *Am. J. Clin. Pathol.* 67(1):20-30; 1977.

A modified orcein staining method was applied to 65 liver biopsies and to 16 stored paraffin-embedded blocks of liver tissue obtained at autopsy from patients with chronic hepatitis to evaluate its efficacy in detecting hepatitis B surface antigen (HBsAg). In every case, the histologic picture was compared with serologic findings for serum HBsAg. Specimens from all six cases of acute hepatitis were orcein-negative (Or$^-$). Of 33 specimens of chronic persistent hepatitis, 15 were Or$^-$, 5 of these were from HBsAg-seropositive (S$^+$) patients; 18 specimens were Or$^+$, 6 of these were also S$^+$. Of 21 chronic active hepatitis specimens, 16 were Or$^+$ (6 also S$^+$) and 5 were Or$^-$ (1 also S$^+$); of 5 cases of primary biliary cirrhosis, 3 were Or$^-$ and 2 were Or$^+$; all were S$^-$. The results appear to support the concept of an inverse relationship between the severity of liver cell damage and the titer of circulating HBsAg. A positive stain may be of value in distinguishing acute from chronic hepatitis when histologic changes are minimal. However, the total of 36 Or$^+$ cases compared with 18 S$^+$ cases make further evaluation necessary. Results with stored autopsy material suggest that the stain may be used in determining the etiology of cirrhosis. Inclusion bodies seen in hepatomas were Or$^+$, indicating that they contain, or are related to, HBsAg.

1520 DISTRIBUTION PATTERNS OF HEPATITIS B SURFACE ANTIGEN (HBsAg) IN THE LIVER BIOPSIES OF HEPATITIS B PATIENTS.

(Eng.) Ray, M. B.; Desmet, V. J. (Academisch Ziekenhuis Sint-Rafael, Katholieke Universiteit, Kapucijnenvoer 33, B-3000 Leuven, Belgium). *Acta Gastroenterol. Belg.* 39 (9/10):307-317; 1976.

The pathogenesis and development of various divergent morphological types of liver diseases associated with hepatitis B antigenemia were studied. Using indirect immunofluorescence on the liver biopsies of hepatitis B patients, four main distribution patterns of hepatitis B surface antigen (HBsAg) were observed: full cytoplasmic fluorescence with diffuse lobular distribution; cytoplasmic fluorescence with spotty distribution; fluorescence in the cell membrane and/or cell peripheries; and focal cytoplasmic positivity. These various expression patterns of HBsAg could be integrated into each type of chronic and acute hepatitis B. Strong, full cytoplasmic fluorescence distributed diffusely in the liver lobules was observed in histologically near-normal liver, chronic persistent hepatitis, and inactive cirrhosis. This corresponded with the presence of groundglass hepatocytes in the biopsies. Membrane-localized HBsAg was minimal or absent in those conditions. HBsAg specific fluorescence in the liver cell membranes and/or peripheral cytoplasm with cytoplasmic fluorescence in a lower number of hepatocytes, was observed in chronic aggressive hepatitis, active cirrhosis, and acute hepatitis with possible transition to chronicity. HBsAg was rarely detected in the liver of patients with acute hepatitis, despite its presence in the blood. These distinctive expression patterns of HBsAg in the liver may fortify the diagnosis of various histologic types of hepatitis B and may indicate an interaction of both hepatitis B virus and host immune response in the pathogenesis of hepatitis B.

1521 NON-A, NON-B HEPATITIS.

(Eng.) Purcell, R. H.; Alter, H. J.; Dienstag, J. L. (Natl. Inst. Allergy and Infectious Diseases, Natl. Inst. Health, Bldg. 7, Room 202, Bethesda, MD 20014). *Yale J. Biol. Med.* 49(3):243-250; 1976.

The epidemiology and clinical characteristics of type non-A, non-B hepatitis are reviewed. Type non-A, non-B hepatitis was first identified in transfused patients. At present, as much as 90% of transfusion-associated hepatitis appears to be type non-A, non-B. The epidemiology of type non-A, non-B hepatitis resembles more closely that of type B hepatitis than that of type A disease. The average incubation period of type non-A, non-B hepatitis appears to be 6-7 weeks shorter than that of type B hepatitis. Type non-A, non-B hepatitis is less acutely severe than type B disease, resulting in a lower proportion of icteric cases and a lower mean maximum SGPT value. Elevation of SGPT values persisting for 6 or more months has been observed more frequently following non-A, non-B hepatitis than following type B hepatitis. In some cases of chronic non-A, non-B hepatitis, periods of transaminase elevation alternate with periods of normal or near normal transaminase activity; these cyclic patterns appear to occur more frequently in chronic non-A, non-B hepatitis than in chronic type B disease Attempts to identify an antigen specific for non-A, non-B hepatitis or to transmit the disease to nonhuman primates have been unsuccessful. Seroepidemiologic evidence indicates that two or more agents may be responsible for non-A, non-B hepatitis. The most effective means of preventing transfusion-associated non-A, non-B hepatitis is the substitution of blood derived from volunteer sources for commercial blood.

1522 VA COOPERATIVE STUDY OF POST-TRANSFUSION HEPATITIS, 1969-1974: INCIDENCE AND CHARACTERISTICS OF HEPATITIS AND RESPONSIBLE RISK FACTORS. (Eng.) Seeff, L. B.; Zimmerman, H. J.; Wright, E. C.; McCollum, R. W. (Veterans Admin. Hosp., 50 Irving St., Washington, DC 20422). *Am. J. Med. Sci.* 270(2):355-362; 1975.

The results of a 6-yr randomized, double-blind study of the incidence, characteristics, and risk factors of post-transfusion hepatitis, using the data from 2,788 patients, are presented. Patients were studied by biochemical and serologic tests within 4 days of transfusion and were followed regularly for 6 months. Tests for hepatitis B surface antigen (HBsAg) were also performed. Minimal diagnostic criteria were set. Patients received two doses of either α-globulin or a placebo. The average number of transfusions received by each patient was 3.4, and 63.2% of the blood was of paid-donor origin. Hepatitis occurred in 316 patients (11.3%). Sixty-two of these were icteric. Retrospective screening of transfused blood by radioimmunoassay showed 0.5 to 1.7% to be HBsAg positive. Thirty-five percent of the patients developed hepatitis of 2 to 6 weeks incubation, and 31% had disease of 13 weeks duration. Duration was unaffected by receipt of immune globulin. The risk of hepatitis increased with the number of paid blood units transfused, yet was independent of the number of volunteer units used. Hepatitis B was significantly more frequent in recipients of HBsAg positive blood (14.9%) than in recipients of either antibody-containing (4.8%) or negative (2.5%) blood. Development of all forms of hepatitis was higher in both antigen and antibody recipients than in negative recipients, suggesting a higher rate of non-B infection with antibody-containing blood than with negative blood. Conversion from the use of commercial donor blood to volunteer donor blood decreased the incidence from 20.8 to 6.2% in one hospital studied. Sensitive screening methods have not decreased the incidence of hepatitis. An additional, undefined agent may be responsible for most instances of post-transfusion hepatitis, and the use of commercial donor blood is the most important factor in the development of hepatitis.

1523 RESEARCH INTO CONDITIONS AFTER VIRAL HEPATITIS. (Slo.) Weisz, P.; Niederland, T. R.; Zacharova, M.; Cervenka, J. (III interna klinika, LF KU NsP akademika, Februaroveho vitazstva 163 P.W., 800 00 Bratislava, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 29(4):225-232; 1975.

Subjective complaints, hepatomegaly, and certain biochemical indices were studied in 182 men and 191 women who had viral hepatitis 10-13 yr previously. The patients were divided into two groups: those whose anamnesis did not show any etiological factors other than viral hepatitis, which might have affected the studied parameters, and those whose anamnesis did show such additional factors. Less than 25% of all the patients had subjective complaints, and such complaints were more often observed in the second group than in the first. Hepatomegaly and pathological laboratory test results (hyperbilirubinemia, elevated GPT activity, elevated BSP retention, and hypergammaglobulinemia) were also more frequent in the second group. Only elevated alkaline phosphatase activity occurred more often in the first group, which may have been a result of the age and sex of those showing elevated levels of this enzyme (preponderance of young men). Studies on long-term sequelae of viral hepatitis are complicated by the difficulty of obtaining data on patients after long periods of time. Only about 20% of the patients contacted were included in this study.

LIVER AND BILIARY TRACT

Chronic Hepatitis

1542 PERIPHERAL BLOOD LYMPHOCYTE POPULATIONS IN CHRONIC LIVER DISEASE. (Eng.) Thomas, H. C.; Freni, M.; Sanchez-Tapias, J.; De Villiers, D.; Jain, S.; Sherlock, S. (Dept. Medicine, Royal Free Hosp., Pond St., Hampstead, London, N.W.3, England). *Clin. Exp. Immunol.* 26(2):222-227; 1976.

Peripheral blood lymphocyte (PBL) concentrations were compared in 16 patients with alcohol-induced liver disease (ALD), 20 patients with primary biliary cirrhosis (PBC), and 23 patients with chronic active hepatitis (CAH) and cirrhosis to determine whether there are any changes peculiar to each disease.

Control data were obtained for 20 healthy subjects. The percentage and concentration of PBL that forms erythrocyte (E) rosettes were significantly decreased ($p<0.05$) in all patient groups compared to controls, but early-antigen (EA) rosette formation was not different from controls. Mature T-lymphocyte concentrations were reduced and Fc receptor-bearing (B and K) lymphocyte concentrations were normal in the patients. Null cells were significantly increased ($p<0.05$) in all patient groups. Treatment of patient lymphocytes with 0.1 ml levamisole (0.24 µg/ml) or thymosin (200 µg/ml) stimulated some null cells to form E-rosettes. In a hepatitis B surface antigen-negative CAH patient, 20 mg prednisolone/day had a beneficial effect, in that it decreased Fc receptor-bearing lymphocyte and null cell concentrations. Changes in PBL concentration were similar in all patient groups and, therefore, are probably secondary effects of liver damage.

1543 THERAPEUTIC AND PROGNOSTIC PROBLEMS OF PROTRACTED HEPATITIS. (Pol.) Kozakiewicz, H.; Stolarczyk, J.; Zielinska, W.; Ellert-Zygadlowska, J.; Jasiel, M.; Imielinska, H. (Klinika Chorob Zakaznych Instytutu Chorob Wewnetrznych AMG, 80-214 Gdansk, ul. Smoluchowskiego 18, Poland). *Pol. Tyg. Lek.* 30(22):949-951; 1975.

The treatment of persistent hepatitis, and its long-term results are discussed. Ninety patients with protracted viral hepatitis were observed for 1-4 yr. After follow-up, a puncture biopsy was performed to ascertain the morphological status of the liver. The patients received a rest cure, "liver" diet, and supportive medication, depending on their condition. Adrenal cortex hormones were administered to 74 patients during the acute stage of the disease, whose symptoms were continuous or remittent jaundice, stubborn dyspeptic disorders, pain in the joints, and discomfort. Prednisone (30-60 mg/day) was given for 3 months in 45 patients, up to 6 months in 10 patients, up to 12 months in 11 patients, and more than 12 months in 8 patients. At the end of the observation period, 58 patients were without complaints; 15 mentioned considerable weakness as a result of physical or mental efforts, dyspeptic symptoms, and intermittent liver and joint aches; and 5 patients were lost to follow up. Palpation showed continued liver enlargement in 47 patients; size and consistency of the organ were normal in the rest. In 30% of the patients, individual deviations from standard liver function tests were seen. Of 38 patients (36.6%) with control biopsies, 6 showed no liver pathology at all, 10 revealed slight regressive changes, and 7 showed persistent and 8, chronic hepatitis. Corticosteroid therapy produced an inhibitory effect on immunological processes and impaired formation of resistance, thus contributing to the duration of the disease. A careful and critical selection of patients for this kind of treatment is indispensable.

1544 ROLE OF CHRONIC HEPATITIS IN DEVELOPMENT OF THALASSAEMIC LIVER DISEASE. (Eng.) Masera, G.; Jean, G.; Gazzola, G.; Novakova, M. (Clinica Pediatrica dell'Universita degli Studi, Via Commenda 9, Milan, Italy). *Arch. Dis. Child.* 51(9):680-685; 1976.

Liver function was studied over a 4-yr period in 90 thalassemic children who were transfused with packed RBC every 20-30 days to maintain a hemoglobin (Hb) level of >7.5-8 g/dl. SGOT and SGPT levels were increased more than three times normal values in 62/90 children, and in 45 of these, raised levels persisted from 9 to 24 months. Nine children were hepatitis B surface antigen (HBsAg)-positive, 2 for 34 and 36 months, resp.; 28 children were anti-HBsAg-positive, 13 for prolonged periods, and 15 for only a few weeks. Liver biopsy of 26 of the patients with prolonged abnormally high transaminase levels revealed chronic persistent hepatitis (CPH) in 14, chronic aggressive hepatitis (CAH) in 9, and hepatic fibrosis in 3. The presence of HBsAg or anti-HBsAg was found in 9/14 CPH patients and in 8/9 CAH patients. Smooth muscle antibodies, rheumatoid factor, and migration inhibition factor were seen in most CAH patients. In all 26 biopsied children, massive siderotic pigmentation involving the hepatocytes, Kupffer cells, and macrophages of the portal spaces and fibrous tissue was noted. These findings support the hypothesis that chronic hepatitis contributes to the development of liver disease in a large number of thalassemic children undergoing transfusion therapy. The various forms of chronic hepatitis had special features that were probably due to the excessive iron overload.

1545 EFFECT OF TREATMENT ON THE COURSE AND OUTCOME OF CHRONIC HEPATITIS IN CHILDREN. (Rus.) Ebels, I. G.; Kartashova, O. I.; Saldava, L. A. (Riga Medical Inst., Stage Pediatric Hosp., Riga, USSR). *Pediatriia* (3):66-69; 1976.

1546 ACUTE "PAINFUL" HEPATITIS: CLINICAL PROBLEMS AND DIFFERENTIAL DIAGNOSIS. (Ita.) Ciammaichella, A.; Solitro, A.; Arcuri, P. (Ospedaliero Generale Regionale, Pio Istituto di S. Spirito ed O.O.R.R. di Roma, Rome, Italy). *G. Mal. Infett. Parassit.* 27(7):445-450; 1975.

LIVER AND BILIARY TRACT

Cirrhosis

1551 FUNCTIONAL STUDY OF THE GASTRIC MUCOSAL BARRIER IN HEPATIC CIRRHOSIS. (Eng.) Solis-Herruzo, J. A.; Pardo-Rueda, J. (Ciudad Sanitaria de la Seguridad Social "1 de Octubre," Departamento de la Medicina Interna, Servicio de Digestivo, Carretera de Andalucia K 4.500, Madrid, Spain). *Acta Hepatogastroenterol. (Stuttg.)* 23(5):351-359; 1976.

The penetration of H^+ through the gastric mucosal barrier was evaluated in 11 patients with hepatic cirrhosis and in 5 normal controls. The fluxes of Na^+, K^+, and Cl^- were also calculated. The mean H^+ flux was -0.42 mEq/15 min for the controls and -3.37 mEq/15 min ($p<0.05$) for the cirrhotics. In two patients, the H^+ back-diffusion was <2 mEq/15 min; in three, it was between 2 and 3 mEq/15 min; and in six, it was >3 mEq/15 min. The mean Cl^- flux was -0.18 mEq/15 min for the controls and -3.74 mEq/15 min ($p<0.05$) for the cirrhotics. In six cirrhotics, Cl^- back-diffusion was greater than the upper limits of normal, reaching a value of -12.73 mEq/15 min in one patient. The mean Na^+ flux was +3.86 and +1.96 mEq/15 min ($p<0.01$) for controls and patients, resp. In the patients, this positive Na^+ flux into the lumen was not parallel to H^+ loss. The mean K^+ flux was +0.26 mEq/15 min for the controls and +0.067 mEq/15 min ($p<0.01$) for the cirrhotics. Subsequent gastric biopsy showed dilatation of the capillaries and edema of the lamina propria in all of the patients. In five patients, there was also extravasation of the RBC; in three, the epithelial cells were desquamated; and in three, atrophic gastritis was present. One patient had melena, due to hemorrhagic gastritis. The cause of the damaged gastric mucosal barrier in the cirrhotics could be due to one or a combination of malnutrition, hypoproteinemia, hypoxia, portal hypertension, or reflux of the biliary salts.

1552 PREOPERATIVE LIVER FUNCTION TESTS CORRELATED WITH ENCEPHALOPATHY AFTER PORTACAVAL ANASTOMOSIS. (Eng.) Kardel, T.; Ramsoe, K.; Rasmussen, S. N. (Osterbrogade 54A, DK-2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(1): 29-32; 1975.

The correlation between preoperative galactose elimination capacity and the incidence and degree of encephalopathy after portacaval anastomosis was investigated. Changes in various liver function parameters were also studied. Portacaval shunt was used to treat 31 patients with liver cirrhosis and bleeding esophageal varices. Of these, 18 had alcoholic cirrhosis, 11 had cryptogenic cirrhosis, and 2 had primary biliary cirrhosis. A side-to-side shunt was performed in 12 and an end-to-side, in 19. The galactose elimination capacity, serum bilirubin and albumin concentrations, and prothrombin time were measured from 2 weeks to 15 months following surgery. The patients were classified into three groups according to the degree of postoperative encephalopathy: poor (severe encephalopathy requiring nursing care); fair (patients without severe encephalopathy); and good (patients with no portasystemic encephalopathy). Six patients died: four from postoperative bleeding, one from cardiac arrest, and one from variceal hemorrhage following thrombosis of the anastomosis. There was a significant deterioration in galactose elimination (median, -26 mg/min), serum bilirubin (median, +0.4 mg/100 ml), and prothrombin time (median, -10%) following shunt. Serum albumin was unchanged. The decrease in galactose elimination correlated significantly with the preoperative value ($p<0.05$). None of the liver function tests discriminated between fatal cases and survivors. The postoperative course was evaluated as poor in 6 cases, fair in 8, and good in 11. The postoperative clinical results correlated significantly with the preoperative galactose elimination and with age at operation ($p<0.001$). Of seven patients with a preoperative value ≤225 mg/min, the postoperative rating was poor in four, fair in two and good in one; five of six patients considered poor were aged over 60 yr. The prognosis was significantly worse in cryptogenic than in alcoholic cirrhosis ($p=0.05$). It is suggested that the poorer results of shunt surgery in the aged may be related to a progressive deterioration of liver function with age.

1553 LIVER VOLUME ESTIMATED BY ULTRASONIC SCANNING BEFORE AND AFTER PORTAL DECOMPRESSION SURGERY.

(Eng.) Rasmussen, S. N.; Kardel, T.; Jorgensen, B. J. (Gentofte Hosp., DK-2900 Hellerup, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(1):25-28; 1975.

The results of liver volume determination by ultrasonic scanning in 12 cirrhotic patients before and after portal decompression surgery are presented. These data are also compared with studies of liver function measured by the galactose elimination capacity. Six patients had alcoholic cirrhosis and six had cryptogenic cirrhosis. Shunt procedures included end-to-side (7 patients), side-to-side (4), and portarenal (1). The preoperative liver volume in alcoholic cirrhosis ranged from 1,695 to 3,483 ml (median, 2,541 ml), and in cryptogenic cirrohsis, from 1,048 to 2,358 ml (median, 1,446 ml). This difference was significant ($p< 0.05$). Liver volume decreased significantly following surgery ($p<0.01$) with a median decrease of 402 ml, or 2% of the preoperative median volume. No significant change in galactose elimination was found. Liver volume and galactose elimination were not correlated preoperatively, but became so after surgery ($p<0.05$). The postoperative liver volume was also correlated with the preoperative galactose elimination ($p<0.01$). The specific galactose elimination showed a median increase of 5 mg/min x 100 ml liver volume ($p<0.05$). It is suggested that after decompression surgery, the liver adapts the volume according to the functional capacity of the parenchyma. The postoperative decrease in liver volume seems to be due to loss of superfluous blood, water, and fat from liver tissue.

1554 FREE AMINO ACIDS IN THE PLASMA AND URINE OF LIVER CIRRHOSIS PATIENTS.

(Cro.) Rosic, D.; Pokrajcic, G.; Obradovic, M.; Rosic, J. (Univ. Hosp., Belgrade, Yugoslavia). *Acta Med. Iugosl.* 29(3):265-270; 1975.

A qualitative and quantitative analysis of free amino acids in the blood plasma (in mg%) and urine (in mg/24 hr) of 10 healthy subjects and 20 decompensated liver cirrhosis patients was conducted by chromatography. In healthy subjects, 23 amino acids were found in the plasma and 25 in the urine, while in liver cirrhosis patients, these figures were 22 and 26, resp. Tryptophan (1.11 mg%) was found in the plasma of normal adults, but not in that of cirrhosis patients. Proline (1.62 mg/24 hr) was present in the urine of cirrhosis patients, but not in that of control subjects. Marked quantitative differences between the concentrations of many amino acids in healthy subjects and those in cirrhotic patients were also noted. Reduced plasma and urine levels of glutamine and methionine and reduced plasma levels of cysteine in patients with cirrhosis suggest that these amino acids may be used in cirrhosis therapy.

1555 DEOXYCHOLIC ACID IN THE THERAPY OF LIVER CIRRHOSIS.

(Cze.) Fassati, P.; Chyle, P.; Fassati, M.; Chyle, M. (Oddeľeni klinicke biochemie, OUNZ, Sokolovska 304, 19061 Prague 9, Czechoslovakia). *Cas. Lek. Cesk.* 114(40):1222-1226; 1975.

Deoxycholic acid (ADOCH) was given *ad nebulas* (0.15 g, b.i.d., for 3 months) to 17 men and 11 women with liver cirrhosis with moderately severe and severe functional disturbances. Treatment was continued for another 3 months in two patients and for up to a year in three patients. A series of over 20 biochemical tests on the blood serum and urine was conducted 6 months before treatment, immediately before treatment, 1 month after the onset of treatment, and at the end of the 3-month treatment period. Statistically significant improvement was observed in 11 of the 19 blood serum tests, with the most noticeable improvement manifested in the BSP curve ($p<0.001$), BSP 45-min retention test ($p<0.001$), albumin turbidity reaction ($p<0.001$), thymol turbidity reaction ($p<0.001$), and GPT ($p<0.001$) and GOT ($p<0.001$) activities. Improvements in other tests were either of low statistical significance or unproven. The subjective condition of most patients also improved. In patients treated longer than 3 months, laboratory tests did not show further significant improvement, but no unfavorable effects were observed. Thus ADOCH had a favorable effect in liver cirrhosis patients, with test results indicating an improvement in protein synthesis, primarily in the albumin fraction. The exact nature of the mechanism of the effect of ADOCH in liver cirrhosis patients is not known.

1556 GASTROINTESTINAL EDEMA IN CIRRHOTICS: RADIOGRAPHIC MANIFESTATIONS AND PATHOGENESIS WITH EMPHASIS ON COLONIC INVOLVEMENT. (Eng.) Balthazar, E. J.; Gade, M. F. (New York Medical Coll.-Metropolitan Hosp. Center, 1901 First Ave., New York, NY 10029). *Gastrointest. Radiol.* 1(3): 215-223; 1976.

Radiologic manifestations of gastrointestinal edema in 22 consecutive patients with advanced liver cirrhosis are described. All patients were chronic alcoholics, and all had portal hypertension, as demonstrated by the presence of varices. In terms of gastric involvement, large gastric folds were occasionally seen in association with typical small bowel changes; involvement was diffuse, with large tortuous rugae being observed in the entire stomach. An irregular contour along the entire circumference of the barium-filled stomach was seen; and the normal, deep, symmetrical peristaltic waves were diminished or absent. Small bowel involvement included irregular thickened mucosal folds and mild dilatation in the duodenum and proximal jejunum; superficial and disorganized peristaltic contractions; free peritoneal fluid; and uncoiling, separation, or centralization of intestinal loops. Reduced distensibility and an irregular contour with an asymmetrical and deformed haustral pattern was observed in a barium-filled colon. Occasionally, a smooth configuration devoid of haustra was seen. The expected shortening of the colon in a postevacuation film did not occur, and visualized mucosal folds showed marked thickening and a distorted pattern that may mimic diffuse nodularity. A significant number of cases (13) showed involvement of the descending colon and the rectosigmoid segment. Involvement of the right side of the colon was a constant feature. These studies suggest that the production of intestinal edema is the result of a complex mechanism involving multiple factors on both sides of the capillary membrane, such as the ability of the lymphatic system to handle excessive flow, the oncotic pressure, the hydrostatic pressure, and portal hypertension with or without venous collaterals. Portal hypertension seems to play a dominant role, since it correlates best with intestinal edema and explains its usual distribution.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

71 THE EVALUATION AND APPLICATION OF ANGIO-
GRAPHY IN DIAGNOSIS OF GALLBLADDER
SEASES. (Jpn.) Kusano, S.; Matsubayashi, T.,
a, S.; Itoh, K.; Horiike, S.; Hiramatsu, K.;
tsuyama, S.; Kitsuki, T. (Kitasato Univ., Sch.
dicine, Asamizodai, Sagamihara, Kanagawa, Japan).
ppon Acta Radiol. 35(12):1069-1081; 1975.

giography was performed on 19 patients with
llbladder cancer, and the angiographic findings
re compared with the histologic and clinical
ndings, to formulate diagnostic standards.
lignancy could be definitely diagnosed upon the
esence of encasement (inside diameter more than
mm) in the cystic artery and arteries adjacent
the gallbladder, and amputation in the branches
the cystic artery. However, abnormal angio-
aphic findings, such as mottled staining and
ovascularity, were found in malignant and
nign gallbladder inflammations. Angiography is
propriate upon nonopacification of the gallbladder
th oral or drip infusion cholecystography, when
lignancy is suspected clinically, or there
need for a preoperative examination.

72 ENDOSCOPIC RETROGRADE INTRAHEPATIC CHO-
LANGIOGRAM: RADIOGRAPHIC FINDINGS IN
TRAHEPATIC DISEASE. (Eng.) Rohrmann, C. A., Jr.;
sel, H. J.; Ayoola, E. A.; Silvis, S. E.; Vennes,
A. (Univ. Washington Sch. Medicine, Seattle, WA
95). *Am. J. Roentgenol.* 128(1):45-52; 1977.

contributions of endoscopic retrograde cho-
giopancreatography (ERC) in diagnosing processes
volving the intrahepatic biliary tree were eval-
ted in 107 patients, and the results were corre-
ted with intrahepatic diagnoses by liver biopsy.
histologic diagnoses were: normal, 6; hepatitis,
cirrhosis, 38; cholestasis, 4; portal fibrosis,
fatty metamorphosis, 3; cholangitis, 22; neoplasia, 13; congenital hepatic fibrosis, 1; and polycystic liver disease, 1. For the normal patients, the ductal characteristics correlated well with those found at biopsy. For the cirrhotics, the cholangiograms showed multiple focal stenoses in 22 patients, decreased arborization in 25, and, to a lesser extent, tortuosity and approximation of the intrahepatic ducts. All five patients with sclerosing cholangitis had abnormal cholangiograms, with focal stenoses in five, focal ectasias in five, and nonobstructing extrahepatic biliary stenoses in two. Chronic cholangitis and portal fibrosis were frequently associated with extrahepatic obstructing lesions and increased intrahepatic ductal caliber, but no distinguishing intrahepatic characteristics. The neoplasias and the case of polycystic liver disease showed mass effects comprising ductal displacement, narrowing, and encasement. The potential of ERC is significant, especially in separating normal from abnormal cases, in distinguishing between intrahepatic processes, and as an adjunct to liver biopsy.

1573 5 YEARS EXPERIENCE IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATICOGRAPHY (ERCP). (Eng.) Belohlavek, D.; Koch, H.; Rosch, W.; Schaffner, O.; Maeder, H. U.; Flory, J.; *et al.* (Medizinische Univ.-Klinik, Krankenhausstr. 12, 8520 Erlangen, W. Germany). *Endoscopy* 8(3):115-118; 1976.

Five years' experience with endoscopic retrograde cholangiopancreaticography (ERCP) is reported, comprising 2,507 investigations in 1,981 patients. The cannulation of at least one ductal system was possible in 93% of the examinations. Pancreatography was successful in 82%, while cholangiography was successful in 63%. Normal anatomy was seen in 51.5% of the investigations. Pathological alterations of the pancreas included irregularities of the ductal system, strictures, pseudocysts, and calculi. Chronic pancreatitis was diagnosed based on these criteria in 405 patients; pancreas carcinoma was diagnosed in 76 patients. The most common pathological findings of the biliary tree were concretions in 168 patients. ERCP proved helpful in the diagnosis of chronic pancreatitis and became mandatory as a preoperative indication of resection. Disorders of the biliary duct can easily be diagnosed by ERCP, especially in the case of obstructive jaundice.

1574 ULTRASONIC VISUALIZATION OF THE NON-OPACIFIED GALLBLADDER: RESPONSE OF THE NORMAL AND OBSTRUCTED CANINE GALLBLADDER TO C8CCK.

(Eng.) Lindstrom, R.; Herman, M. W.; Tabrisky, J.; Castagna, J. (Harbor General Hosp., 1000 W. Carson St., Torrance, CA 90509). *Invest. Radiol.* 11(5): 464-471; 1976.

In vivo studies in normal dog gallbladders and *in vitro* studies with a simulated gallbladder were carried out to determine whether B-scan ultrasonography is as reliable as radiography in measuring changes in volume of the organ. The width or planimetric area of the sonogram correlated with the change in balloon volume and with similar radiographic measurements. *In vivo* measurements of the normal canine gallbladder stimulated by a carefully prescribed infusion of the C-terminal octapeptide of cholecystokinin (2.2-5.5 ng/kg/min for 8-10 min) showed a clearly defined decrease in gallbladder width. In ligation and division of the common bile duct, no change in gallbladder size was demonstrated. It is concluded that sonography alone can be used to measure a change in gallbladder size to better differentiate complete obstruction of the common bile duct from medical causes in the jaundiced patient.

1575 SIGNIFICANCE OF ENZYMATIC CHANGES IN THE SERUM IN DISEASES OF THE BILE DUCTS.

(Cze.) Ninger, E. (Onkologicky ustav, Bayerova 40, 602 00 Brno, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 29(8):547-553; 1975.

A review of literature indicates that in acute flare-ups and complications of gallbladder and biliary tract diseases, enzyme changes in the serum involving both excretory and indicator enzymes of the liver are relatively frequent. The cause of these changes is primarily cholestasis, and they are more frequent and more marked in a clinical course with jaundice. The activity levels of individual hepatic enzymes in the serum differ, depending on the sensitivity of their response to cholestasis. Knowledge of these enzyme changes, although they are not absolutely specific for biliary tract diseases, can supplement the clinical picture in difficult cases. In chronic biliary tract diseases in the asymptomatic phase, the majority of the blood enzyme pictures are poorly or only slightly different from the normal, and cannot in themselves serve to differentiate chronic biliary tract disease from inactive chronic hepatopathies.

1576 INFLUENCE OF CHOLIC AND CHENODEOXYCHOLIC ACID ON CANALICULAR BILE FLOW IN MAN.

(Eng.) Lindblad, L.; Schersten, T. (Surgical Metabolic Research Lab., Sahlgrenska sjukhuset, Univ. Goteborg, S-413 45 Goteborg, Sweden). *Gastroenterology* 76(6):1121-1124; 1976.

Hepatic bile flow was measured, and hepatic [^{14}C]mannitol clearance was calculated, during depletion of the bile pool and during duodenal administration of cholic (1 g/hr) or chenodeoxycholic acid (1 g/hr) in 10 patients. The patients had undergone surgery for uncomplicated gallstone disease 7-12 days earlier. The biliary mannitol clearance correlated significantly with the bile flow. During depletion of the bile acid pool and during duodenal infusion of both cholic and chenodeoxycholic acid, the bile to plasma ratio of [^{14}C]mannitol was significantly less than unity (0.74 ± 0.01), indicating that the mannitol clearance was lower than bile flow. Linear relations between the bile acid secretion rate and bile flow and between the bile acid secretion rate and [^{14}C]mannitol clearance were found during depletion of the bile acid pool (secretion of cholic, chenodeoxycholic, and deoxycholic acids; relative concentration, 1.0:1.0:0.5 g), as well as during cholic acid infusion (73 ± 3% cholic acid in the secreted hepatic bile) and during chenodeoxycholic acid infusion (88 ± 2% chenodeoxycholic acid in the secreted hepatic bile). The bile flow dependence on bile acids (0.011 ± 0.002 ml/µmol) was not significantly different for mixed bile acid secretion or mainly cholic acid or chenodeoxycholic acid secretion. The ductular bile flow (0.08 ± 0.03 ml/min) was not significantly influenced by the various experimental conditions. The canalicular flow, the bile acid independent flow (0.17 ± 0.05 ml/min), and the bile acid dependent flow, constituted 70-85% of the total bile flow. It is concluded that secretion of cholic acid and of chenodeoxycholic acid promotes the same bile flow volume per µmol in man.

1577 CRITICAL SEQUELAE IN BILIARY TRACT DISEASE.

(Eng.) Glenn, F. (Cornell Univ. Medical Coll., New York, NY). *Am. Surg.* 42(10):735-743; 1976.

Critical sequelae in calculous biliary tract disease are reviewed. The more common of these are acute cholecystitis, choledocholithiasis, acute obstructive suppurative cholangitis, biliary enteric fistula, liver abscess, related pancreatitis, and biliary cirrhosis. Principle etiological factors that contribute to the pathological changes of acute cholecystitis, a sequela of gallstones, are obstruction, infection, and ischemia; obstruction in calculous disease is by far the most common initiating cause. Retention of calculi in the ductal system following cholecystectomy and/or common duct exploration with or without demonstrating choledocholithiasis is always a potential problem; and the older the patient, the greater the likelihood of choledocholithiasis in the presence of cholelithiasis. Obstruction and infection are common manifestations of biliary tract disease; when complete obstruction to bile flow occurs within the common duct or in one or more of the major intrahepatic ducts in the presence of pathogenic enteric bacteria, a catastrophic syndrome, characterized by sudden severe right upper quadrant abdominal pain, often develops. Biliary enteric fistulas are a complication of longstanding and far advanced biliary tract disease; in the majority of cases, there is perforation of the gallbladder with the discharge of a stone or stones into the lumen of an adherent viscus, usually the intestine. Intrahepatic pyogenic abscess usually follows recurrent cholangitis associated with calculous disease with obstruction. The diagnosis of pancreatitis associated with calculous biliary tract disease is confirmed by elevation of pancreatic enzymes (normal range; amylase, 40-140 and lipase, 0.2-2.0 ml of 0.10 sodium hydroxide/ml serum). The mortality rate (estimated 20%) is high in the severe acute forms of pancreatitis. Biliary cirrhosis is not infrequently seen in patients over 65 yr of age with a small contracted gallbladder containing stones and with stones in the common duct.

1578 ON THE MEDIATION OF INFLAMMATORY REACTION IN THE HUMAN GALLBLADDER EPITHELIUM.

(Eng.) Sjodahl, R.; Tagesson, C. (Dept. Surgery, Linkoping Univ., Linkoping, Sweden). *Scand. J. Gastroenterol.* 11(3):321-328; 1976.

The lysosomes of the human gallbladder epithelium were investigated to determine their relation to the subcellular localization of phospholipase activity. Homogenates of human gallbladder epithelium obtained at cholecystectomy were prepared, and the specific activities (activity/mg protein) of six different acid hydrolases were determined. The highest activities were noted for *N*-acetyl-β-glucosaminidase (9×10^{-2}) and acid phosphatase (3×10^{-2}), while only minor activities of β-galactosidase (7×10^{-7}) and β-xylosidase (7×10^{-7}) were recorded. Activities of β-glucuronidase (4×10^{-3}), β-glucosidase (2×10^{-4}), and β-fucosidase (1×10^{-4}) were in between. The phospholipase activity in the homogenized gallbladder epithelium was then 1.5 nmol lecithin hydrolyzed/min/mg protein. All the enzymes exhibited structure-linked latency. When the subcellular organelles were analytically separated by density gradient centrifugation at 100,000 *g* for 1 hr, particles containing acid glycosidases were recovered at a sucrose density of 1.18-1.19, while the mitochondrial marker enzyme succinate-reductase accumulated at a density of 1.16. The bulk of sedimentable phospholipase activity was recovered with particles sedimenting at 1.18-1.19. The results suggest that phospholipase is present in lysosomes of the human gallbladder epithelium.

1579 SEMIQUANTITATIVE MEASUREMENT OF LITHOCHOLIC ACID COMPOUNDS IN BILE FROM PATIENTS WITH GALLSTONES, BEFORE AND DURING TREATMENT WITH CHENODEOXYCHOLIC ACID.

(Eng.) Arnfred, T.; Pedersen, L. (Dept. Clinical Chemistry, Aalborg Sygehus, afsnit Nord, DK-9100 Aalborg, Denmark). *Scand. J. Gastroenterol.* 11(5):497-504; 1976.

A method for two-dimensional thin-layer chromatography of unprocessed bile is described. The method was used in the analysis of duodenal bile from 14 healthy subjects, 6 untreated patients with gallstones, and the same 6 patients after treatment with chenodeoxycholic acid. The method gives distinct spots from lithocholic acid and its compounds with glycine, taurine, and sulfuric acid. The size of the spots is estimated by comparison with standard spots, and the concentrations of individual bile acids are expressed as a fraction of the total content of bile acids in the sample. The concentration of total lithocholic acid was found to be 1-3% (mean 1.5%) of the total concentration of bile acids in duodenal bile from the healthy persons. It was slightly higher in bile from six untreated patients with gallstones, and still higher, 3-7% (mean 4.0%) in bile from the same patients during chenodeoxycholic acid treatment. The difference between the concentrations of total lithocholic acid in the bile samples from healthy persons and from patients treated with chenodeoxycholic acid was statistically significant ($p<0.01$). Nearly all the lithocholic acid was conjugated with glycine or taurine, and approximately half of it was sulfated. The increase in the total lithocholic acid concentration in the bile from patients consisted of glycine conjugates. Two-dimensional thin-layer chromatography may be useful for identifying toxic side-effects of chenodeoxycholic acid therapy for gallstones.

1580 HORMONAL THERAPY AND CHOLELITHIASIS.

(Eng.) Weiss, G. N.; Weiss, E. B. (1611 Foster St., Lake Charles, LA 70601). *Int. Surg.* 61(9):472-474; 1976.

A brief review correlating hormonal therapy with an increased incidence of cholelithiasis in younger women is presented. A study of 1,346 cholecystectomies indicated that the incidence of gallbladder surgery in women under 40 yr of age increased 7.4% between 1969 and 1973. Among women who had taken hormonal medication, the incidence of surgery was far greater in those under 30 yr of age than in those aged 30-39. Both incidences far exceeded those in groups of similar age that had not received hormonal therapy. Studies have shown that cholelithiasis is nearly always the result of mechanical obstruction, which in turn is due to alterations in the chemistry of the bile or disturbances in biliary function. During pregnancy, the gallbladder is affected by the general smooth muscle atony of the entire digestive system, resulting in slow emptying of the gallbladder. BSP excretion had been found to be decreased 27% in pregnant women, a result that could be duplicated in nonpregnant women by the administration of estrogens. In one study, it was estimated that the annual attack-rate of surgically proven gallbladder disease in otherwise healthy women is about 79/100,000 in those who do not use oral contraceptives, and about twice as high in those who do. It is concluded that hormonal medication is responsible for the increased incidence of cholecystectomies in the younger woman. The incidence of gallbladder disease in young women is expected to increase in the coming years.

1581 THE BETA-CHOLESTEROL IN CHOLESTASIS OF PREGNANCY. II. ENZYMATIC CHANGES IN BLOOD SERUM SAMPLES FROM WOMEN WITH CHOLESTASIS IN PREGNANCY VERSUS THE CHOLESTEROL CONCENTRATIONS IN BETA-LIPOPROTEIN FRACTIONS. (Pol.) Wankowicz, Z.; Roszkowski, I.; Wojcicka, J. (II. Klinika Poloznictwa i Ginekologii IPG AM, 00-315 Warsaw, ul. Karowa 2, Poland). *Ginekol. Pol.* 46(11):1147-1158; 1975.

A possible link between higher cholesterol concentrations in pre-beta and beta-lipoprotein fractions in the serum of pregnant women with cholestasis and extent of liver damage is reported. The level of alanine and asparagine aminotransferases (ALAT and ASPAT, resp.), alkaline phosphatase (total and thermostable), and ceruloplasmin concentrations in the blood were ascertained in 36 women with pregnancy-induced intrahepatic cholestasis. The women were divided into groups according to the level of activity of the enzymes indicated. In the group with an ASPAT activity of below 100 U, a beta-cholesterol concentration of 216 ± 51.6 mg% was noted; in the group with an ASPAT activity of 101-320 U, the beta-cholesterol concentration was 242 ± 40.9 mg%. The same results obtained when the patients were divided into high and low activity groups for ALAT. These values, as well as those for alkaline phosphatase and ceruloplasmin were not statistically significant. Thus, it could not be demonstrated that higher cholesterol concentrations in pre-beta and beta-lipoprotein fractions in women with pregnancy-induced cholestasis could be linked to the activity level of the enzymes mentioned.

GENERAL

1644 DEGRADATION OF BLOOD GROUP ANTIGENS IN HUMAN COLON ECOSYSTEMS. II. A GENE INTERACTION IN MAN THAT AFFECTS THE FECAL POPULATION DENSITY OF CERTAIN ENTERIC BACTERIA. (Eng.) Hoskins, L. C.; Boulding, E. T. (Veterans Admin. Hosp., Cleveland, OH 44106). *J. Clin. Invest.* 57(1):74-82; 1976.

The population densities of fecal bacteria that produce A- and H-degrading activities were estimated in feces of 22 healthy subjects by determining the greatest dilution of feces that yielded A, B, or H blood group degrading enzyme activity after 24 hr incubation in anaerobic cultures. Comparatively small populations of fecal bacteria produced blood group degrading enzymes; their estimated populations were 2 x 10^{-8} g or less in 21 subjects. Fecal populations of B-degrading bacteria were stable over extended periods, and their population density averaged 50,000-fold greater in blood group B secretors than in other subjects. This was due, in part, to a competitive nutritional advantage gained by their ability to enzymatically cleave the B antigenic determinant α-D-galactose from gut mucins of B secretors. Estimated populations of bacteria producing B-degrading activity differed from those producing either A- or H-degrading activity by more than 100-fold in 11 subjects and by 100-fold in 3 subjects. This strongly suggests that B-degrading activity is produced by a different population of bacteria than A- or H-degrading activity. These findings suggest that adaptation of blood group degrading enzymes to mucin structures in human colon ecosystems is chiefly by mutation selection of comparatively small populations of constitutive enzyme producing strains, rather than by substrate-induced enzyme synthesis in many strains.

1645 INTRAEPITHELIAL LYMPHOCYTE COUNTS IN SMALL INTESTINAL BIOPSIES FROM CHILDREN WITH DIARRHOEA. (Eng.) Ferguson, A.; McClure, J. P.; Townley, R. R. W. (Western General Hosp., Edinburgh, EH4 2XU Scotland). *Acta Pediatr. Scand.* 65(5):541-546; 1976.

Small intestinal biopsies from 16 children with celiac disease, 14 with acute gastroenteritis, 12 with failure to thrive, 9 with giardiasis, and 7 normal children were investigated to determine whether a high intraepithelial lymphocyte count is a feature specific to celiac disease or whether it is always associated with partial or subtotal villous atrophy. The normal range for children's intraepithelial lymphocyte counts was similar to that for adults (approximately 6-40 lymphocytes/100 epithelial cells). Lymphocyte counts were high in celiac disease, but were also high in some children with giardiasis or with failure to thrive in whom jejunal biopsy appeared otherwise normal. Intraepithelial lymphocyte counts were normal in acute gastroenteritis, even when there was partial villous atrophy with increased lamina propria lymphoid cell infiltrate. The measurement of small intestinal lymphocyte infiltration may be of diagnostic value in differentiating the diarrhea of food intolerance from infectious diarrhea in young children.

GENERAL

Parasitology

1709 HEPATIC ARTERY HYPERTROPHY AND SINUSOIDAL HYPERTENSION IN ADVANCED SCHISTOSOMIASIS. (Eng.) Paes Alves, C. A.; Rabelo Alves, A.; Abreu, W. N.; Andrade, Z. A. (Rua Padre Feijo, 31 Anexo 1 Faculdade Medicina, 4000 Salvador, Bahia, Brazil). *Gastroenterology* 72(1):126-128; 1977.

To test the hypothesis that arterial hypertrophy causes the sinusoidal hypertension in advanced schistosomiasis, the wedged hepatic vein pressure was determined in five patients with hepatosplenic schistosomiasis and sinusoidal hypertension and in one control patient, before, during, and after clamping the main trunk of the hepatic artery. The wedged hepatic pressure in the five patients varied from 20.7 to 35.4 mm Hg. While the catheter was in an occluded position within the hepatic vein and the patients were undergoing splenectomy, the main trunk of the hepatic artery was clamped. The sinusoidal pressure then fell to levels that varied from 3.7 to 7.4 mm Hg, but returned to previous levels when the clamping was released. Wedged hepatic venous pressure levels, which were significantly greater than portal venous pressure values, decreased minimally after splenectomy. Portal venous pressure levels, however, fell to 63% of presplenectomy levels. In the control case with an enlarged spleen (cavernous hemangioma), but with a normal liver, the wedged hepatic pressure was 7.4 mm Hg and showed no alteration after clamping of the hepatic artery. These data point out the importance of hepatic artery hypertrophy in causing elevation of the wedged hepatic pressure in advanced hepatic schistosomiasis.

GENERAL

Regional Enteritis

1730 IMMUNOHISTOCHEMICAL CHARACTERIZATION OF LOCAL IMMUNOGLOBULIN FORMATION IN CROHN'S DISEASE OF THE ILEUM. (Eng.) Baklien, K.; Brandtzaeg, P. (Medical Dept. A., Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 11(5):447-457; 1976.

Paired direct immunofluorescence was used to localize and differentially enumerate immunocytes containing the various immunoglobulin (Ig) classes in ileal bowel walls of 10 patients with Crohn's disease and 7 control patients. In slightly inflamed mucosa, the total number of Ig-containing cells of an average "tissue unit" increased threefold, compared with normal controls, but only minor changes occurred in class ratios. In severely inflamed mucosa with persisting glands, the total immunocyte number was increased by a factor of 12.2, compared with the control unit. For IgA, IgM, and IgG cells, this increase was 9.0, 12.0, and 60.9, resp. The immunocyte ratios for these three major Ig classes were 57.5:14.7:27.7 in the inflamed mucosa and 83.1:11.4:5.4 in the histologically normal control mucosa. When severely inflamed specimens from the ileum and from the colon were compared, there was no statistically significant difference in absolute immunocyte counts or class distributions. IgD and IgE immunocytes were extremely rare, and no consistent increase was found in the inflamed mucosae. In both the ileum and the colon, fairly dense immunocyte populations with a marked IgG-cell predominance were encountered in the deeper layers of the inflamed bowel wall. This study confirms that a pronounced local activation of the B-cell system takes place in inflammatory bowel disease, and shows that a progressive deviation from the characteristic secretory Ig response occurs in association with increasing severity of the inflammatory process.

1731 SERUM LYSOZYME IN CROHN'S DISEASE: A USEFUL INDEX OF DISEASE ACTIVITY. (Eng.) Falchuk, K. R.; Perrotto, J. L.; Isselbacher, K. J. (Harvard Medical Sch., Boston, MA). *Gastroenterology* 69(4):893-896; 1975.

The correlation between serum lysozyme concentration and the degree of activity of the inflammatory process in Crohn's disease (CD) was evaluated in 51 patients with CD and in 25 controls. The serum lysozyme concentration was measured only in patients with blood urea nitrogen levels lower than 22 mg/100 ml. Lysozyme levels in controls were 8.8 ± 0.4 µg/ml; in active CD, the levels were 20.8 ± 0.8 µg/ml; and in inactive CD, the levels were 10.4 ± 0.7 µg/ml. The mean lysozyme concentration for active CD patients was significantly higher than that for inactive CD patients ($p<0.001$) or controls ($p<0.001$). There was no significant difference between inactive CD and controls. In active CD cases, the correlation of lysozyme level to degree of activity was: mild, 15.6 µg/ml; moderate, 20 µg/ml; and severe, 25 µg/ml. Only patients with moderate or severe cases of CD had significantly elevated lysozyme concentrations ($p<0.02$ and $p<0.01$, resp.). Serum lysozyme levels increased with exacerbation of the disease process and decreased with any clinical improvement. Serum lysozyme concentrations may be useful as an indicator of the activity of CD and as an aid in monitoring the therapeutic responses.

1732 ANERGY TO DINITROCHLOROBENZENE AND DEPRESSION OF T-LYMPHOCYTES IN CROHN'S DISEASE AND ULCERATIVE COLITIS. (Eng.) Meyers, S.; Sachar, D. B.; Taub, R. N.; Janowitz, H. D. (Mount Sinai Hosp., New York, NY 10029). *Gut* 17(11):911-915; 1976.

To evaluate cellular immunity in patients with inflammatory bowel disease, skin reactivity to dinitrochlorobenzene (DNCB) and levels of circulating T-lymphocytes were measured in 15 patients with ulcerative colitis, 15 patients with Crohn's disease, and 12 normal control subjects. Diminished reactivity to DNCB was demonstrated in 87% of patients with Crohn's disease ($p<0.001$) and in 53% with ulcerative colitis ($p<0.02$), as compared with only 8.5% of controls; anergy was more frequent in Crohn's disease than in ulcerative colitis ($p<0.05$). Levels of circulating T-lymphocytes were also depressed in both Crohn's disease and ulcerative colitis ($p<0.001$) as compared with controls, the values in Crohn's disease being lower than those in ulcerative colitis ($p<0.02$). There were no correlations of DNCB response with extent, duration, or severity of disease or with T-cell levels within any patient group. These data provide further support for the concept that there is impairment of cell-mediated immunity among many patients with chronic inflammatory bowel disease.

1733 ANAL LESIONS COMPLICATING CROHN DISEASE. (Eng.) Homan, W. P.; Tang, C. K.; Thorbjarnarson, B. (New York Hosp., 525 E. 68th St., New York, NY 10021). *Arch. Surg.* 111(12):1333-1335; 1976.

Of 503 patients with Crohn's disease, 138 (28%) developed an anorectal abscess, anal fissure, or anal fistula during the course of the disease. In 9.3% of patients, the anal lesion preceded the onset of intestinal symptoms by 2 weeks to 12 yr. Patients with large bowel disease were twice as likely to develop an anal lesion as were patients with small bowel disease. Likewise, patients with large bowel disease were twice as likely to have had an anal lesion as a presenting symptom. A patient with an anal lesion, however, was more apt to develop small bowel disease simply because the small bowel was a far commoner site of Crohn's disease in this series. Specific evidence of Crohn's disease was not found in histological examination of material from any of the patients. The cause of the anal lesions is still not clear.

1734 HYPERALIMENTATION IN INFLAMMATORY BOWEL DISEASE. "SURGICAL" AND "NONSURGICAL" ROLES. (Eng.) Ruberg, R. L.; Steiger, E. (Ohio State Univ. Coll. Medicine, Columbus, OH). *Ohio State Med. J.* 72(6):363-365; 1976.

1735 ARE THE INFLAMMATORY BOWEL DISEASES IMMUNE COMPLEX DISEASES? (Eng.) Thayer, W. R., Jr. (Dept. Biological Medical Sciences, Brown Univ., Providence, RI). *Gastroenterology* 70(1):136-137; 1976.

1736 ANTI-INFLAMMATORY DRUG TREATMENT IN CROHN'S DISEASE. (Eng.) Goldstein, F.; Thornton, J. J.; Abramson, J. (231-232 Lankenau Medical Bldg., Philadelphia, PA 19151). *Am. J. Gastroenterol.* 66(3):251-258; 1976.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

46 ULTRASTRUCTURAL SUBSTRATE OF THE EXOCRINE
PANCREATIC SECRETORY CHANGES FOLLOWING
TAL VAGOTOMY (AN EXPERIMENTAL INVESTIGATION).
um.) Nana, M.; Neumann, E.; Dancea, S. (Clinica
irurgicala I, Romania). *Cluj. Med.* 48(1):49-52;
75.

preclinical study of the functional significance
ultrastructural morphologic modification in the
ocrine pancreas following vagotomy is presented.
e observations were made in pancreas specimens
llected from dogs at 2.5-3 months after truncal
sterior vagotomy, and examined by electron micros-
py (14,120x enlargement). Disturbances in zymo-
nesis were correlated with mitochondrial and
clear modifications in the acinar cells. The
tochondria were fewer, of normal size but with
sorganized cristae, or very small but morphologi-
lly normal. Some formed a homogenous mass due to
e disappearance of the mitochondrial membrane
showed a broken membrane slightly detached from
e endoplasmic reticulum. The nuclei were of
equal size, and had reduced perinuclear space and
creased electron microscopic optical density;
e apical pole region showed large vesicles of
ozymogen with decreased electron microscopic
tical density (prozymogen lakes). It is suggested
at the results would explain the decrease in the
sponse velocity and quantity of enzymes in the
ncreatic juice of vagotomized subjects, even
ter stimulation with physostigmine. These inves-
gations have established the necessity of selective
sterior vagotomy in the surgical treatment of
cers. The vagotomy would insure normal postopera-
ve pancreatic function, even under conditions of
ximal digestive stimulation.

7 EXOCRINE PANCREAS OF STREPTOZOTOCIN-
DIABETES RATS TREATED WITH INSULIN.
g.) Yagihashi, S. (Hirosaki Univ. Sch. Medicine,
osaki, Japan). *Tohoku J. Exp. Med.* 120(1):31-42;
76.

effect of insulin treatment on the exocrine pan-
eas of female Wistar rats with streptozotocin-
luced (50 mg/kg, i.v.) diabetes was investigated
light and electron microscopy. In diabetic rats
eated with daily lente insulin (8-20 U/day)
ection for 4 weeks, the islets became hyperplastic
proliferative, although degenerative and atrophic
ets caused by streptozotocin remained if the rats
e not treated with insulin. Fibrosis and de-
eration of the acinar cells were not found in
the diabetic rats by light microscopy. Elec-
n microscopy showed that acinar cells of the
crine pancreas of the diabetic rats that re-
ved no insulin treatment were characterized
irregular dilatation and prominent lamellar
angement of rough endoplasmic reticulum
by nuclear pyknosis. One hour after a single
ection of insulin (6 U/kg, s.c.), the rough
oplasmic reticulum of the acinar cells of the
betic rats was activated, and many intracisternal
granules appeared. When the insulin injections were continued, the acinar cells showed regular arrangement of rough endoplasmic reticulum, much less vacuolization, and fewer immature zymogen granules in comparison with those of the untreated diabetic rats. The exocrine pancreas of the insulin-treated rats contained many autophagic vacuoles, which were thought to be derived from lysosomes. These results suggest that insulin has a repairing effect on damaged acinar cells.

1748 ONSET OF CELL PROLIFERATION IN THE SHORTENED GUT: RAPID HYPERPLASIA AFTER JEJUNAL RESECTION. (Eng.) Obertop, H.; Nundy, S.; Malamud, D.; Malt, R. A. (Shriners Burns Inst. and Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 72(2):267-270; 1977.

Early manifestations of cell proliferation were studied in the large and small intestine of young female Sprague-Dawley rats after resection of the proximal one-third of the small bowel. On the day after resection, the absolute amounts of RNA and DNA increased in gut distal to the resection. As compared with values from sham-resected gut, nucleic acid levels in much of the distal small bowel and colon increased. Increased specific activity in DNA after the injection of [^{3}H]thymidine was present in the small bowel on the second day, when there was an increase of 77% in the mid small bowel from resected gut, as compared with transected gut. Changes were marked and persistent in the midgut for 10 days, tending to be less intense and of shorter duration in progressively more distal segments. Compensatory cell proliferation in midgut occurs within 2 days of jejunectomy. Identifiable proliferative responses appearing within 2 days of enterectomy provide a model for observing the response to humoral substances transferred by vascular parabiosis.

1749 ONSET OF CELL PROLIFERATION IN THE SHORTENED GUT: COLONIC HYPERPLASIA AFTER ILEAL RESECTION. (Eng.) Nundy, S.; Malamud, D.; Obertop, H.; Sczerban, J.; Malt, R. A. (Shriners Burns Inst. and Massachusetts General Hosp., Boston, MA 12114). *Gastroenterology* 72(2):263-266; 1977.

Because cell proliferation in the small bowel is greatest distal to a resected segment, and because passive dilation of the colon seems unusual compared with compensatory proliferative responses of other organs, the cytokinetics of the rat colon after ileal resection were studied. The RNA content of the transverse colon was increased 32% after 7 days; after 14 days the increase was present throughout the colon. The DNA content of the ascending colon increased 29% after 10 days. Specific activity of DNA labeled with [^{3}H]methylthymidine was elevated 29% in the ascending colon and 49% in the descending colon on the 7th postoperative day. Colonic cell proliferation was stimulated within 1 week of ileal resection. Since colonic hyperplasia precedes neoplasia, the proliferative response in colon to removal of the ileum may precondition the large bowel to the action of putative neoplastic agents in the succus entericus.

1750 RINCINOLEIC ACID EFFECTS ON RABBIT INTESTINE: AN ULTRASTRUCTURAL STUDY. (Eng.)

Gaginella, T. S.; Lewis, J. C.; Phillips, S. F. (Mayo Graduate Sch. Medicine, Univ. Minnesota, Rochester, MN). *Mayo Clin. Proc.* 51(9):569-573; 1976.

Lanthanum hydroxide and ruthenium red were used as extracellular markers to study the ultrastructural effects of rininoleic acid on rabbit intestinal epithelium. In fasting animals, segments of ileum or colon were perfused for 60 min *in vivo* with buffer containing 10 mM sodium ricinoleate. Biopsy specimens were obtained from both areas of the intestine after perfusion with both control buffer and ricinoleate. Ricinoleate did not alter ruthenium or lanthanum staining in the zona occludens, zona adherens, or macula adherens of the ileal or colonic epithelium. The results suggest that ricinoleate does not cause fluid secretion by selectively disrupting the junctional areas between cells.

1751 THE DISTRIBUTION AND EARLY MORPHOLOGY OF THE CHRONIC GASTRIC MUCOSAL REACTION.

(Eng.) Lawson, H. H. (Baragwanath Hosp., Johannesburg, South Africa). *Br. J. Surg.* 63(8):585-588; 1976.

The early histological appearances of the established chronic gastric mucosal reaction (CGMR) that occurs as a result of the exposure of gastric mucosa to duodenal contents were studied in six dogs, and the reactions of different areas of the stomach to this stimulus were compared. The animals underwent a preoperative gastric biopsy and were killed 3, 6, and 12 months after Finney pyloroplasty or Billroth I gastrectomy. After either procedure, no area of the stomach was more susceptible to CGMR than other areas. Three months after surgery, epithelial proliferation was seen in the stomachs of dogs that underwent pyloroplasty, and epithelial proliferation and pseudopyloric metaplasia were seen in the gastrectomized animals. Six months after either type of surgery, intestinal metaplasia, pseudopyloric metaplasia, and mamillation were present, together with epithelial proliferation. At 3 and 6 months, the area of CGMR was greater in the animals that had undergone partial gastrectomy than that in the animals that had undergone pyloroplasty. Although CGMR was seen in the anterior wall 6 months after partial gastrectomy, this area appeared surprisingly normal after 1 yr.

1752 MODEL FOR THE STRUCTURE OF THE GASTRIC MUCOUS GEL.

(Eng.) Allen, A.; Pain, R. H.; Robson, T. R. (Medical Sch., Univ. Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, England). *Nature* 264(5581):88-89; 1976.

On the basis of information in the literature on the molecular structure of gastric mucous gel, the following model is proposed: the gel is composed of highly expanded, solution-filling glycoprotein molecules, when packed together, interact at or near their surfaces. Each glycoprotein molecule consists of four equal sized subunits joined by disulfid bridges. Each glycoprotein subunit consists of a protein core (14% by weight), with attached carbohydrate side chains. The protein core has two regions. One region is rich in serine, threonine, and proline and bears all the carbohydrate. The other region, of amino acid composition characteristic of globular protein, contains cystine residues that bridge the four subunits. A large proportion of the solvent is thus intramolecular, and the polymer extends more or less evenly throughout the gel. This model predicts that gel formation at a given concentration should be markedly dependent on the effective volume in solution of the glycoprotein molecule.

1753 POPULATION KINETICS OF ANTRAL GASTRIN CELLS IN THE MOUSE.

(Eng.) Lehy, T.; Willems, G. (INSERM U.-10, Hopital Bichat, 75877 Paris CEDEX 18, France). *Gastroenterology* 71(4): 614-619; 1976.

The proliferation of antral gastrin cells was studied in adult male Swiss mice. The immunoperoxidase identification on semithin Epon sections of the antral gastrin cells was combined with radioautography after single or multiple injections of [^{3}H]-thymidine. After a single injection, the nuclear uptake of [^{3}H]thymidine was observed in 0.25% of the well-differentiated gastrin cells. Ten days after six successive injections of the precursor, the labeling index reached 4.5%, indicating that the renewal of the gastrin cell population is very slow. The turnover time was estimated to be 2-4 months. Analysis of the labeling index curves obtained during and after the administration of [^{3}H]thymidine confirmed that the majority of the gastrin cells wer renewed through replication of other gastrin cells, although differentiation of a fraction of this gastrin cell population from other cells in the antrum cannot be excluded.

1754 DISTRIBUTION OF GASTRIN IN CANINE, CAT, AND HUMAN DIGESTIVE ORGANS.

(Eng.) Tobe, T.; Chen, S. T.; Hemmi, K.; Fukuchi, K. (Kyoto Univ. Medical Sch., Kyoto, 606, Japan). *Am. J. Surg.* 132(5):581-582; 1976.

The distributions of gastrin in the digestive organs of dogs and cats were determined by highly specific immunofluorescence, and these distributions were compared with that in humans. In the dogs and cats, sections were obtained from the antrum, body, and cardia of the stomach and from the duodenum, esophagus, jejunum, ileum, colon, pancreas, parotid gland, and submandibular gland. As in humans, gastrin-containing cells were found only in the antrum and duodenum of the dogs and cats. In the dogs and cats, however, gastrin-containing cells were concentrated in the duodenal bulb, and none occurred distal to the papilla of Vater.

1755 ON THE INTRINSIC INNERVATION OF NORMAL RAT LIVER: HISTOCHEMICAL AND SCANNING ELECTRON MICROSCOPICAL STUDIES. (Eng.) Skaaring, P.; Bierring, F. (Winslow Inst. Human Anatomy, Univ. Odense, DK-5000 Odense, Denmark). *Cell Tissue Res.* 171(2):141-155; 1976.

The innervation of normal rat liver was studied histochemically and by scanning electron microscopy (SEM). Using the Bodian method, stained fibers were observed in the lobules, and with the modified Karnovsky and Roots thiocholine method, cholinesterase [presumably acetylcholinesterase (AChE)]-positive nerve fibers were found in a pattern similar to that of the Bodian-stained fibers. The AChE-positive nerve fibers formed a network in the liver lobules in close relation to hepatocytes and sinusoids. Fluorescent varicose nerve fibers demonstrated by the glyoxylic acid and Falck-Hillarp fluorescence methods were found only in the interlobular spaces associated with vessels. As no overlapping of distribution patterns of AChE-positive nerve fibers and fluorescent nerve fibers occurred, the AChE activity of the nerves of the liver lobules probably reflects the associated presence of acetylcholine in the nerve fibers. Nerves of the liver lobules thus may belong to the autonomic parasympathetic nervous system. SEM revealed light cords apparently situated in smooth-surfaced channels between adjacent hepatocytes and in the space of Disse, where fibers also cross sinusoids. The cords of the SEM may represent the AChE-positive nerve fibers of the light microscopic observations.

1756 PANCREATIC DUCT CELLS: METABOLIC AND BIOCHEMICAL CHARACTERIZATION [Abstract]. (Eng.) Singh, M.; Parks, N. M.; Webster, P. D., III. (Veterans Admin. Hosp., Augusta, GA). *Clin. Res.* 25(1):50A; 1977.

1757 ISOLATION OF FUNCTIONALLY AND MORPHOLOGICALLY INTACT PANCREATIC DUCT CELLS OF THE RAT [Abstract]. (Eng.) Folsch, U. R.; Fischer, H.; Soling, H. D.; Creutzfeldt, W. (Dept. Medicine, Univ. Gottingen, Gottingen, W. Germany). *Scand. J. Gastroenterol.* 11(41):24; 1976.

1758 SPECIFIC BINDING OF [^{3}H] CAERULEIN ON RAT PANCREATIC PLASMA MEMBRANES: BINDING CHARACTERISTICS AND CORRELATION WITH ADENYLATE CYCLASE ACTIVATION [Abstract]. (Eng.) Deschodt-Lanckman, M.; Robberecht, P.; Christophe, J. (Medical Sch., Free Univ. Brussels, Brussels, Belgium). *Scand. J. Gastroenterol.* 11(41):81; 1976.

1759 THE CONTRIBUTIONS OF PANCREATIC AND BILIARY SECRETIONS AND FOOD TO THE MAINTENANCE OF MORPHOLOGY AND EPITHELIAL REPLACEMENT IN THE RAT SMALL INTESTINE [Abstract]. (Eng.) Clarke, R. M.; Ecknauer, R.; Feyerabend, G. (Depts. Clinical Chemistry and Surgery, Univ. Ulm, Ulm, W. Germany). *J. Anat.* 122(3):718-719; 1976.

1760 EPITHELIAL KINETICS IN SMALL INTESTINE OF ORALLY VS INTRAVENOUSLY ALIMENTED RATS [Abstract]. (Eng.) Assad, R. T.; Eastwood, G. L.; (West Roxbury Veterans Admin. Hosp., Boston, MA). *Clin. Res.* 24(5):627A; 1976.

1761 ADHERENCE OF E. coli TO IMMATURE INTESTINE IS MEDIATED BY MUCOSAL RECEPTORS OF MANNOSE-SPECIFIC BACTERIAL LECTINS [Abstract]. (Eng.) Thaler, M. M.; Hirschberger, M.; Mirelman, D. (Dept. Pediatrics, Univ. California, San Francisco, CA). *Clin. Res.* 25(3):469A; 1977.

1766 ELECTRICAL PROPERTIES OF PIG COLONIC MUCOSA MEASURED DURING EARLY POST-NATAL DEVELOPMENT.

(Eng.) Henin, S.; Smith, M. W. (Istituto di Fisiologia Generale, Via Mangiagalli 32, 20123 Milan, Italy). *J. Physiol. (Lond.)* 262(1):169-187; 1976.

Microvillar membrane (V_m) and transmural (V_t) potential differences were measured in proximal colon taken from pigs at birth and up to 10 days of age to determine whether data obtained in the pig are similar to that reported previously for other preparations of mammalian large intestine. In addition, the effect of early development on microvillar membrane permeability was investigated. V_m remained independent of the age of the animal, provided that it was measured in the absence of methionine. The over-all mean was -43.3 mV. Adding 3 mM methionine to fluid bathing the mucosal surface of newborn pig colon caused a 9.8 mV depolarization of V_m and a 6.7 mV increase in V_t. These effects, which were Na^+-dependent, were not seen in 10-day-old animals. Substituting SO_4^{2-} for Cl^- in methionine-free medium caused a hyperpolarization in V_m. Increasing the concentration of K^+ caused a corresponding depolarization. The substitution of choline for Na^+ had no effect on V_m. Cl^- and K^+ movement across the microvillar membrane together accounted for the bulk of the measured membrane potential. These results applied to all stages of development. Na^+ uptake across the microvillar membrane of the newborn pig colon was increased in the presence of methionine. This effect disappeared in older animals. Na^+ uptake in the absence of methionine doubled during the first 24 hr of postnatal life. This increase was maintained using colons taken from older animals. Methionine depolarization of V_m in the new-born pig colon is probably caused by the electrogenic influx of Na^+. The ability of the colon to actively concentrate methionine within its mucosa disappears at the same time as methionine ceases to affect V_m and V_t. Methionine and Na^+ may form a ternary complex with a carrier in the brush border of the new-born pig colon, and this carrier may be lost or modified during early postnatal development.

1767 EFFECTS OF ELECTRICAL GRADIENTS ON VOLUME FLOWS ACROSS GALL BLADDER EPITHELIUM.

(Eng.) Van Os, C. H.; Michels, J. A.; Slegers, J. F. G. (Univ. California Medical Center, Los Angeles, CA 90024) *Biochim. Biophys. Acta* 443(3): 545-555; 1976.

By continuous volumetric measurement of water flow across rabbit gallbladder epithelium, the effects of electrical gradients upon actively transporting and nontransporting (oubain-inhibited) tissues were investigated. Gallbladders were mounted as flat preparations between two half-chambers filled with Ringer solution. The mucosal solution was continuously circulated while the fluid level of a small capillary in the serosal solution was monitored photometrically to record volume flow through the epithelium. Current passing across gallbladder epithelium resulted in water flow toward the negative electrode. The water flow and osmotic potential induced by current in nontransporting membranes were entirely due to polarization of salts in the unstirred layers on either side of the membrane. Osmotic flow in nontransporting bladders was three times greater from mucosa to serosa than vice versa, and was linearly related to the current density between 300 and 900 μA in either direction. Active transport was inhibited by the addition of thiocyanate ions, indicating an anion-sensitive ATPase activity. The importance of $(Na^+ + K^+)$-ATPase in fluid reabsorption was also suggested by the Na^+/ATP ratio, which correlated well with values reported for other tissues. Volume flow across actively transporting membranes in the presence of a 200-μA current in either direction was enhanced or decreased twice as much as would be expected in a nontransporting membrane. The current-induced salt polarization interfered with the natural gradients produced by the active transport mechanism. Volume flows in actively transporting tissues were found to be twice those obtained with gallbladder sac preparations, presumably due to the greater aeration and stirring possible with the volumetric method.

1768 PROTON TRANSPORT BY GASTRIC MEMBRANE VESICLES.

(Eng.) Chang, H.; Saccomani, G.; Rabon, E.; Schackmann, R.; Sachs, G. (Lab. Membrane Biology, Univ. Alabama in Birmingham, Birmingham, AL 35294). *Biochim. Biophys. Acta* 464(2):313-327; 1977.

Proton (H^+) transport by gastric membrane vesicles was studied. A highly purified membrane fraction was derived from hog gastric mucosa by a combination of differential and density gradient centrifugation and free flow electrophoresis. This final fraction was 35-fold enriched with respect to cation activated ouabain-insensitive ATPase. The addition of ATP to this fraction or the density gradient fraction resulted in H^+ uptake into an osmotically sensitive space. The apparent Km for ATP was 1.7×10^{-4} M in the absence of a potassium (K^+) gradient. The reaction was specific for ATP, and both the rate and maximal uptake of H^+ were a function of the nature of the cation, with the sequence in descending order being K^+, rubidium, cesium, sodium, and lithium. The reaction was inhibited by ATPase inhibitors such as *N,N'*-dicyclohexylcarbodiimide. Maximal H^+ uptake occurred with an outward K^+ gradient, but the minimal apparent association constant was found in the absence of a K^+ gradient. The pH optimum for H^+ uptake was between 5.8 and 6.2, correcting for the change in H^+ released by the ATPase reaction. This corresponds generally to the pH optimum of phosphorylation of the enzyme but is considerably less than the pH maximum of the K^+-dependent dephosphorylation. In the presence of an inward K^+ gradient, protonophores, such as tetrachlorsalicylanilide, only partially abolished the H^+ gradient, while valinomycin dissipated 75% of the gradient, and nigericin abolished the gradient. The vesicles thus have a low K^+ conductance, but a measurable H^+ conductance; hence, a K^+ gradient can produce an H^+ gradient in the presence of valinomycin. The uptake and spontaneous leakage of H^+ were temperature sensitive, with the temperature optimum for uptake being 37 C. Ultraviolet ir-

diation inactivated ATPase and H$^+$ transport at
e same rate, approximately twice that of *p*-
trophenylphosphatase inactivation. It is con-
uded that H$^+$ uptake in these vesicles is probably
e to a dimeric (H$^+$ + K$^+$)-ATPase and is probably
nelectrogenic.

69 ELECTROLYTE TRANSPORT BY GALLBLADDERS OF
RABBIT AND GUINEA PIG: EFFECT OF AMPHO-
RICIN B AND EVIDENCE OF RHEOGENIC Na TRANSPORT.
ng.) Rose, R. C.; Nahrwold, D. L. (Milton S. Hershey
dical Center, 500 University Drive, Hershey, PA
033). *J. Membr. Biol.* 29(1/2):1-22; 1976.

n transport and electrical properties of rabbit and
inea pig gallbladders were investigated to gain
rther information about the active transport
echanism that mediates fluid absorption. The intra-
llular and transepithelial electrical potentials
re measured simultaneously with the microelectrode
chnique. Exposure of the mucosal surface to
photericin B (40 μg/ml) resulted in the prompt
velopment of a serosal-positive electrical poten-
ial difference (PD), which could not be attributed to
alteration in ion diffusion potentials across
ither the cell membrane or across the tight junc-
ion. Amphotericin B-induced PD was immediately
ependent on warm temperatures and O$_2$ and was in-
ependent of Na and K concentration gradients across
e cell membrane, suggesting that active ion trans-
ort is directly responsible for the PD. PD was
bolished in the absence of Na in the bathing solu-
ions, indicating that a rheogenic Na pump may be
nvolved; this pump also appeared to be operative
n tissue not exposed to amphotericin B. The
esults indicate that ion transport by rabbit gall-
ladder *in vitro* is a consequence of a rheogenic
ctive Na transport mechanism at the basolateral
embranes, which, in conjunction with a coupled
aCl influx process at the mucosal border ulti-
ately results in absorption of NaCl and water.

770 INTESTINAL ADAPTATION TO DIETARY CALCIUM
RESTRICTION: IN VIVO CECAL AND COLONIC
ALCIUM TRANSPORT IN THE RAT. (Eng.) Petith, M.
.; Schedl, H. P. (Univ. Iowa Hosp., Iowa City,
A 52242). *Gastroenterology* 71(6):1039-1042; 1976.

o examine the role of the cecum and colon in cal-
ium homeostasis, weight-matched growing Sprague-
awley rats were placed on semisynthetic diets
ontaining 1.2 or 0.02% calcium. After 3-4 weeks,
et calcium movements in cecum and colon (large
owel excluding cecum and distal rectum) were stud-
ed *in vivo* by perfusing a 0.4, 0.8, or 3.4 mM
alcium solution. In animals taking 1.2% calcium,
he cecum absorbed calcium actively at 0.8 mM; the
olon showed net secretion except at 3.4 mM. In
alcium-restricted animals, the cecum absorbed at
ll concentrations; the colon reduced secretion at
.4 mM, converted to net absorption at 0.8 mM, and
reatly increased net absorption at 3.4 mM. These
bservations suggest that the large intestine may
ave a role in calcium homeostasis, particularly
hen dietary calcium is restricted.

1771 INHIBITION OF INTESTINAL IRON ABSORPTION BY LAUNDRY STARCH. (Eng.) Thomas, F. B.; Falko, J. M.; Zuckerman, K. (N-937 University Hosp., Ohio State Univ., 410 W. 10th Ave., Columbus, OH 43210). *Gastroenterology* 71(6):1028-1032; 1976.

In vitro and *in vivo* studies were carried out in female Sprague-Dawley rats to determine the effect of laundry starch on the intestinal absorption of inorganic and hemoglobin iron. *In vitro*, laundry starch bound 19-80% of the available ^{59}FeSO$_4$ and 34-68% of the available ^{59}Fe-hemoglobin. Binding of both forms of iron was pH-dependent, with maximal binding at pH 7.0. *In vivo*, laundry starch significantly inhibited mucosal uptake of ^{59}FeSO$_4$ from isolated duodenal loops. In nonanemic rats, the administration of laundry starch (100 mg) 1 hr before a 100-μg dose of ^{59}FeSO$_4$ significantly decreased the absorption of ^{59}FeSO$_4$, as compared to saline or low iron chow controls (6.2 ± 2.0 versus 14.9 ± 2.1 and 11.8 ± 1.7, resp., $p<0.001$). In anemic rats, the absorption of either a 100-μg dose of ^{59}FeSO$_4$ or a 500-μg dose of ^{59}Fe-hemoglobin was also significantly decreased by prior administration of laundry starch. The data indicate that laundry starch binds appreciable quantities of inorganic and hemoglobin iron *in vitro*; inhibits the mucosal uptake of inorganic iron by isolated intestinal loops; inhibits the intestinal absorption of inorganic iron in normal nonanemic rats; and blunts the compensatory increase in inorganic and organic iron absorption in anemic rats. The ingestion of large quantities of laundry starch by patients with amylophagia may inhibit iron absorption and contribute to the development of the iron deficiency anemia seen in these patients.

1772 THE ABSORPTION OF ACETYLSALICYLIC ACID FROM THE STOMACH IN RELATION TO INTRAGASTRIC pH. (Eng.) Dotevall, G.; Ekenved, G. (Sahlgren's Hosp., Univ. Goteborg, Goteborg, Sweden). *Scand. J. Clin. Lab. Invest.* 36(6):801-805; 1976.

The effects of buffered (pH 6.5) versus unbuffered (pH 2.9) solutions of acetylsalicylic acid (ASA) on gastric pH, gastric emptying, and gastric absorption of ASA were studied in 10 healthy volunteers. The buffered solution contained 500 mg ASA, 500 mg citric acid, and 1,250 mg sodium bicarbonate in 150 ml water. The unbuffered test solution contained 500 mg ASA dissolved in 150 ml water. Both test solutions also contained 35 mg of phenol red, which was used as nonabsorbable marker. The mean pH of the first aspirate from subjects given the buffered solution was 3.4 (range, 1.8-6.2), in comparison with a mean pH of 2.0 (range, 1.8-2.2) for the first aspirate from subjects given the unbuffered solution of ASA. Total recoveries of phenol red and ASA were significantly larger for the unbuffered test solution than for the buffered one ($p<0.05$). The mean phenol red and ASA recoveries for subjects given the buffered ASA solution were 12.7% (range, 0.0-48.3%) and 12.4% (range, 0.4-50.3%), resp., as compared with 28.7% (range, 0.3-84.8%) and 22.7% (range, 0.7-78.2%), resp., for subjects given unbuffered solution. Peak plasma salicylate concentrations were virtually the same with buffered and unbuffered ASA test solutions. These results support the theory that the reduced gastric side-effects with effervescent buffered ASA tablets, might be ascribed to a reduced gastric absorption of ASA.

1773 STRUCTURAL LOCUS OF TRANSMUCOSAL ALBUMIN EFFLUX IN CANINE ILEUM: A FLUORESCENT STUDY.

(Eng.) Granger, D. N.; Cook, B. H.; Taylor, A. E. (Univ. Mississippi Sch. Medicine, 2500 N. State St., Jackson, MS 39216). *Gastroenterology* 71(6):1023-1027; 1976.

The histological locus (villus tips versus crypts) of plasma protein loss in the small intestine after elevation of intestinal venous pressure was determined by using the Evans blue-albumin fluorescence technique in dog ileum. Evans blue was mixed with a solution of bovine serum albumin at concentrations that yield negligible amounts of free dye. Control ileal samples were obtained to visualize the natural tissue morphology and fluorescence. The Evans blue-albumin solution was injected, and tissue samples were obtained 15 and 60 min postinjection, then venous outflow was occluded, and after 15 and 60 min, the tissues were sampled. No leakage sites were apparent at normal venous pressures. However, after elevation of venous pressure, Evans blue-albumin was observed in the interepithelial and/or intraepithelial spaces of villus tips, but no Evans blue-albumin was observed either between or within the epithelial cells of the crypts or within the tubular crypt lumina. These results indicate that at elevated venous pressures, the transmucosal albumin flux occurs exclusively at the villus tip region, suggesting a great vulnerability of the cells found in this region to elevations in tissue pressure, as compared to the crypt epithelial cells.

1774 INFLUENCE OF VIABILITY ON BROMOSULFOPHTHALEIN UPTAKE BY ISOLATED HEPATOCYTES.

(Eng.) Schwenk, M.; Burr, R.; Pfaff, E. (Institut fur Toxikologie der Universitat Tubingen, Wilhemstrasse 56, D-7400 Tubingen, W. Germany). *Naunyn-Schmiedeberg's Arch. Pharmacol.* 295(1):99-102; 1976.

BSP uptake was studied as a function of hepatocyte viability in isolated liver cells. Hepatocyte viability was decreased by ageing on storage as a concentrated stock suspension at 2 C. Viability was judged by trypan blue stainability, membrane potential, and respiratory parameters indicative for energy state, substrate supply, and plasma membrane permeability changes. At high BSP concentrations, BSP uptake increased concomitantly with impaired viability; at low concentrations, BSP decreased, with a crossover point at 10 μM. The crossover point was manifest in an increase in K_m (7 ± 3 μM with viable cells and 25-66 μM for cells with low viability) and V (2.7 % 1.6 nmol/mg protein x min with viable cells; 7-10 nmol/mg x min with low viability). Simultaneously, the affinity and size of the membrane-bound fraction decreased. The results support the hypothesis that it is the decreased uptake from plasma to liver that is responsible for the prolonged plasma retention times in the liver function test of patients with impaired hepatobiliary function.

1775 LECITHIN INHIBITS FATTY ACID AND BILE SALT ABSORPTION FROM RAT SMALL INTESTINE IN VIVO.

(Eng.) Saunders, D. R.; Sillery, J. (Dept. Medicine, Univ. Washington, Seattle, WA 98195). *Lipids* 11(12):830-832; 1976.

To test the hypothesis that an impairment in small intestinal lecithin hydrolysis would result in a depression of free fatty acid (FFA) and bile salt absorption, isolated segments of rat small intestine were infused *in vivo* with micellar solutions of 2 mM linoleic acid and 10 mM taurocholate to which was added 3 mM 1-palmitoyl, 2-oleoyl lecithin, or 1-palmitoyl lysolecithin. Absorption of FFA and bile salt was measured under steady state conditions using a single-pass technique. Lecithin depressed the rate of FFA absorption by 40% ($p<0.025$) in jejunal and ileal segments, whereas lysolecithin was associated with normal rates of FFA absorption. Lecithin also reduced taurocholate absorption from the ileum by 30% ($p<0.05$). These data support the hypothesis that lecithin may depress FFA and bile salt absorption from the small intestine in pancreatic insufficiency.

1776 STUDIES ON TRANSLOCATION OF IMMUNOGLOBULINS ACROSS INTESTINAL EPITHELIUM. II. IMMUNOELECTRON-MICROSCOPIC LOCALIZATION OF IMMUNOGLOBULINS AND SECRETORY COMPONENT IN HUMAN INTESTINAL MUCOSA.

(Eng.) Brown, W. R.; Isobe, Y.; Nakane, P. K. (Veterans Admin. Hosp., 1055 Clermont St., Denver, CO 80220). *Gastroenterology* 71(6):985-995; 1976.

To define mechanisms involved in the transport of immunoglobulins into intestinal fluids, IgM, IgA, IgG, and secretory component (SC) were localized in human intestinal mucosa by the peroxidase-labeled antibody technique. Light microscopy revealed that immunocytes containing IgA, IgM, or IgG were located in the lamina propria. IgA, IgM, and SC were prominent in the epithelium of gland crypts. IgG was limited to a few cells at villous tips. At the electron microscopic level, SC was localized to perinuclear spaces, endoplasmic reticulum, saccules associated with Golgi complexes, cytoplasmic vesicles, and lateral and basal plasma membranes of columnar epithelial cells. IgA and IgM, but not IgG, also were localized to plasma membranes and cytoplasmic vesicles of these cells. Neither the immunoglobulins nor SC was found within other types of epithelial cells (Paneth, goblet, endocrine). The findings suggest that the site of SC synthesis in intestinal epithelium is secretory columnar cells, principally those in gland crypts; that the polymeric IgM and IgA are translocated through such SC-containing cells by a process involving the formation of cytoplasmic vesicles; that IgM and IgA could combine with SC during transcellular transport (likely sites are lateral or basal plasma membranes or supranuclear cytoplasm); and that the monomeric IgG does not share the transepithelial cell route involved in IgM and IgA transport.

7 METHOD FOR STUDYING THE INTESTINAL ABSORPTION OF MONOSACCHARIDES IN VIVO IN THE RAT.

.) Galluser, M.; Pousse, A.; Ferard, G.; Gren-
, J. F. (UER Sciences Pharmaceutiques, Rue de
gonne, 67083 Strasbourg, France). *Biomedicine*
):127-132; 1976.

thod for *in vivo* perfusion of isolated jejunal
ileal loops with catheterization of the efferent
s in male Wistar rats is described. A segment
he jejunum and a segment of the ileum, each 20
ong, were isolated. Ringer's solution, with
-labeled D-glucose (5.5 mM), was perfused through
lumen of the isolated segments at the rate of
ml/min. The iliac arteries were catheterized
a simultaneous perfusion of blood pooled from
rats. Hemodynamic and histological results
ed the isolated segments retained the ability to
rb D-glucose for 1 hr. D-glucose was absorbed
er by the jejunum (0.217 μM/min/g) than by the
m (0.095 μM/min/g, $p<0.01$). This experimental
ocol appears to be the method of choice for the
y of the process of absorption in the intestinal
sa.

3 RELATIONSHIPS BETWEEN MUCOSAL HYDROLYSIS AND TRANSPORT OF TWO PHENYLALANINE DIPEP-
ES.

(Eng.) Silk, D. B. A.; Nicholson, J. A.;
, Y. S. (King's Coll. Hosp., London S.E.5, Eng-
). *Gut* 17(11):870-876; 1976.

dies were carried out to investigate the source
free amino acids found in the gut lumen during
rption of dipeptides and to determine the role
rush border peptidases in the mucosal hydro-
is of dipeptides during absorption. The rates
dipeptide disappearance and appearance of hydro-
c products were measured during perfusion of
jejunum and ileum *in vivo* with buffered and
ffered 10 mM solutions of glycyl-L-phenylalanine
-Phe) and L-phenylalanyl-glycine (Phe-Gly).
sal brush border peptidase activity was then
ured in the perfused segments *in vitro* at luminal
nd at two substrate concentrations. In addition,
sol peptidase activity in the perfused segments
measured at pH 7.4 and at 10 mM substrate con-
rations. In the jejunum, there was a relation
een rates of free phenylalanine appearance
ivo (Phe-Gly>Gly-Phe) and rates of brush border
-Gly>Gly-Phe) rather than cytosol (Gly-Phe>Phe-
) peptidase activities. No constant relation
een free phenylalanine appearance and hydrolysis
he dipeptides by either brush border or cytosol
idases was observed in the ileal studies. These
ings suggest that hydrolytic products in the
num originate from the surface of the cell, where-
ydrolytic products in the ileum originate from
the intracellular compartment and the surface
he mucosal cell. In the jejunum, *in vitro* rates
rush border hydrolysis of Gly-Phe were always
than *in vivo* disappearance rates, whereas rates
Phe-Gly brush border hydrolysis always exceeded
nal disappearance rates. These data imply that
-Phe is predominantly transported intact and
rolysed by cytosol peptidase. In contrast, brush
der peptidases play an important role in the
osal hydrolysis of Phe-Gly.

1779 INHIBITORY EFFECT OF PANCREATIC JUICE ON THE INTESTINAL UPTAKE OF VITAMIN B_{12}.

(Eng.) von der Lippe, G. (N-5016 Haukeland sykehus, Bergen, Norway). *Scand. J. Gastroenterol.* 11(7):697-703; 1976.

Studies were carried out to determine whether rat pancreatic juice (RPJ) is able to inhibit the intestinal uptake of vitamin B_{12}-intrinsic factor. RPJ reduced the mean uptake of $^{57}CoB_{12}$ bound to rat intrinsic factor (IF) by perfused rat intestinal segments from 30.1 ± 2.4 pg $^{57}CoB_{12}$/cm intestine to 26.7 ± 2.4 pg/cm ($p<0.05$). RPJ activated with enterokinase reduced the uptake from 22.8 ± 2.8 pg/cm to 16.1 ± 1.9 ($p<0.05$). RPJ also reduced the uptake from 15.8 ± 2.3 pg/cm to 8.3 ± 2.0 pg/cm ($p<0.01$) in segments from partially pancreatectomized rats. Rat bile abolished the inhibitory effect of RPJ. The results indicate that in the absence of bile, the exocrine pancreatic secretion is capable of inhibiting the intestinal uptake of vitamin B_{12}.

1780 THE ABSORPTION OF VITAMIN B_{12} AFTER SUBTOTAL PANCREATECTOMY IN THE RAT.

(Eng.) von der Lippe, G. (N-5016 Haukeland sykehus, Bergen, Norway). *Scand. J. Gastroenterol.* 11(7):683-688; 1976.

Vitamin B_{12} absorption was studied in male Wistar rats after they had undergone subtotal pancreatectomy by a new method. Except for a small remnant along the splenal hilus, the gland was completely removed. Exocrine pancreatic insufficiency was confirmed by fat and nitrogen malabsorption, and moderate diabetes mellitus was seen. Insulin substitution or diet restriction was unnecessary. The absorption of vitamin B_{12} after the p.o. administration of $^{57}CoB_{12}$ (10 ng) was 5.0 ± 0.2 ng $^{57}CoB_{12}$ in unoperated rats and 5.1 ± 0.1 ng in pancreatectomized rats ($p<0.05$). The p.o. administration of pancreatic extract (PE, 100 mg) increased the mean absorption of $^{57}CoB_{12}$ in unoperated rats to 129.3 ± 7.9% of the absorption of $^{57}CoB_{12}$ given alone ($p<0.01$), but not in pancreatectomized rats ($p<0.2$). PE (300 mg) reduced the absorption in unoperated rats to 46.1 ± 5.3% ($p<0.01$). The results indicate that an optimal amount of pancreatic secretion may stimulate the absorption of vitamin B_{12}.

1781 EFFECT OF SEROTONIN ON WATER AND ELECTROLYTE TRANSPORT IN THE IN VIVO RABBIT SMALL INTESTINE.

(Eng.) Kisloff, B.; Moore, E. W. (Medical Coll. Virginia, Richmond, VA 23298). *Gastroenterology* 71(6):1033-1038; 1976.

The influence of i.v.-administered serotonin on water and electrolyte fluxes in the *in vivo* rabbit jejunum and ileum and the effect of glucose on serotonin-induced changes were examined. The animals were divided into four groups: those receiving saline, i.v., while a glucose-free isotonic saline solution perfused the jejunum and ileum;

those given serotonin (20 µg/kg/min), i.v., while glucose-free intestinal perfusate was used as in group 1; those given i.v. saline, while a 10 mM glucose-isotonic saline solution perfused the jejunum and ileum; and those given i.v. serotonin, while the intestinal perfusate was used as in group 3. Serotonin administration resulted in highly significant net secretion of H_2O and sodium in both jejunum and ileum in the groups with a glucose-free perfusate. In the jejunum, serotonin evoked net water and sodium secretion (+42.0 µl/cm/hr and +5.6 µEq/cm/hr, resp.), whereas controls absorbed water and sodium (-16.1 µl/cm/hr and -3.4 µEq/cm/hr, resp., $p<0.001$ for both water and sodium). In the ileum, serotonin significantly enhanced net water (from 59.4 to 127.4 µl/cm/hr, $p<0.001$) and net Na secretion (from 1.7 to 8.0 µEq/cm/hr, $p<0.001$). The addition of glucose to the perfusate completely abolished the serotonin effect. Unidirectional ^{22}Na flux analysis revealed a marked diminution in both mucosal to serosal and serosal to mucosal fluxes in serotonin-treated animals. The decrease in mucosal to serosal flux was greater than the decrease in serosal to mucosal flux, thus explaining the enhanced net secretion observed with serotonin in the groups receiving glucose-free perfusate. In spite of its pronounced effect on water and electrolyte transport, serotonin failed to produce any detectable histological alterations in small bowel mucosa, either by light or electron microscopy. Serotonin may be an important mediator of the diarrhea seen in the carcinoid syndrome, because of its effects on small intestinal H_2O and electrolyte transport.

1782 INTESTINAL ABSORPTION OF DRUGS FROM SOLUBILIZED SYSTEMS OF LONG-CHAIN FATTY ACIDS IN THE RAT. (Eng.) Inui, K. I.; Shintomi, M.; Hori, R.; Sezaki, H. (Hiroshima Univ. Sch. Medicine, Kasumi 1-2-3, Hiroshima, Japan). *Chem. Pharm. Bull.* 24(10):2504-2508; 1976.

2 TRANSDUCER FOR RECORDING ELECTRICAL AND MECHANICAL CHRONIC INTESTINAL ACTIVITY.

;.) Lambert, A.; Eloy, R.; Grenier, J. F. (Unite
INSERM, Surgical Res. and Biophysiopathology
he Intestine, 67200 Strasbourg Hautepierre,
ce). *J. Appl. Physiol.* 41(6):942-945; 1976.

xtraluminal displacement transducer for simul-
ously recording the mechanical activity in
perpendicular directions and the electrical
vity of the intestinal serosa is described.
length variations in two perpendicular directions
measured by means of strain gauges bonded on
pairs of lamellae embedded in a rigid stand.
electrical activity was recorded by means of
electrodes placed at the extremity of these
llae. The electrical gauges of each pair of
llae are connected to form a Wheatstone bridge.
device allows the establishment of a correla-
between the mechanical displacement of the
stinal wall serosa and electrical potentials
eans of long-term studies.

3 ELECTRICAL POTENTIAL OF GASTRODUODENAL MUCOSA MEASURED BY ENDOSCOPY. (Eng.)

ino, G. E.; Ascher, N. V.; Borner, J. W.; Johnson,
J.; Goodale, R. L. (Dept. Surgery, Univ. Minne-
Health Sciences Center, Minneapolis, MN).
. Gynecol. Obstet. 144(1):8-12; 1977.

troduodenal mucosal electrical potentials were
sured in 33 patients with inflammatory-ulcerative
ions and in 17 healthy controls. The negative
ctrical potential of the gastroduodenal mucosa
respect to the blood stream was measured by
necting a potentiometer to an i.v. and an intra-
tric electrode. A fiberoptic gastroduodenoscope
used to introduce and position the probe elec-
de into the stomach and duodenum. Recordings tak-
in nine patients with gastric ulcers ranged from
to -26 mV, in comparison with normal readings that
e generally over -30 and as high as -50 mV.
drops in potential difference from normal for 6
ients with acute gastritis, 2 with chronic gastri-
, 1 with atrophic gastritis, 14 with erosive
ions, and 3 with erosive-hemorrhagic lesions were
3.6, 17 ± 7.1, 29 ± 7.7, 18 ± 5.1, and 27 ± 4.2
resp. Potential difference values measured in
e duodenal ulcer patients were also consistentlyy
ow normal levels, and the potential difference
p in the duodenum had an absolute value that
ged from -4 to -7 mV. In general, a deflection
the potential difference value toward zero
racterized any disruption of the normal
osa. Localized lesions reproduced localized
ential difference deflections, and atrophic le-
ns were represented by larger areas of abnormal po-
tial difference levels. Direct multiple deter-
ations of potential differences over mucosal
as in which lesions are suspected is a useful
simple tool for more objective gastroduodenosco-
diagnoses.

4 INTRALUMINAL PRESSURE IN THE SIGMOID COLON. I. METHOD AND RESULTS IN NORMAL

JECTS. (Eng.) Weinreich, J.; Andersen, D. (Surgical Univ. Clinic I, Aarhus Amtssygehus, DK-8000 Aarhus C, Denmark). *Scand. J. Gastroenterol.* 11(6): 577-580; 1976.

A modified method for the measurement of intraluminal pressure in the sigmoid colon and the results of experiments in which 12 healthy subjects underwent the procedure 30 min after the i.v. administration of 0.5 mg neostigmine are described. The bowel is prepared by a single phosphate enema, followed by overnight fasting. Two catheters are placed 10 and 25 cm from the anal verge through a sigmoidoscope. The higher catheter is inserted blindly from the rectosigmoid junction, minimizing the need for air insufflation and making the examination more tolerable for the subject. The position is checked after visualization of the catheters by 10 ml of water soluble contrast medium. Water is infused continuously through the catheters for fecal clearing. The median motility index was 597, with a range of 125 to 1,169. Variance analysis of repeated measurements showed that variation from subject to subject exceeded the day-to-day variation ($p<0.01$). Identical results were obtained for mean wave amplitude and activity percentage. The interperson variation also exceeded variation in computation of records ($p<0.01$ for all three parameters). Mean wave amplitude, activity percentage, and motility index increased in one patient who was given increasing doses of neostigmine (0.25, 0.5, and 1.0 mg). This technique reduces the total examination time to about 75 min. It gives an acceptably low day-to-day variation, and demonstrates the range of variation between normal persons as a frame of reference for later comparison with groups of patients with colonic disorders.

1825 INSULIN RESISTANCE AND RELATED ELECTRICAL ACTIVITY OF THE SMALL INTESTINE. (Eng.)

Ruckebusch, M.; Weekes, T. E. C. (Ecole Nationale Veterinaire, 23, chemin des Capelles, F-31076 Toulouse Cedex, France). *Experientia* 32(9):1163-1165; 1976.

To test the hypothesis that endogenous insulin plays a role in the control of small intestinal electrical activity, the postprandial intestinal electrical activity was studied in hyperinsulinemic and normal Zucker rats and in an insulin-resistant dog. Five obese and five lean Zucker rats were allowed food *ad libitum* from 1800-0800 hr over a 6-week period. The previously described pattern of migrating myoelectric complex (MMC) was seen from 0800 to 1800 hr (food withheld), and the postprandial pattern (i.e., continuous spiking with randomly occurring spike bursts) was seen from 1800 to 0800 hr in both lean and obese rats. However, the postprandial disruption of the MMC was of longer duration in the obese rats than in the nonhyperinsulinemic animals the mean number of MMC per hour averaging 2.6-3.4 in the latter and 1.2-1.6 in the former. No postprandial disruption was seen in an insulin-resistant dog. The results support the concept that insulin plays a major role in the control of gut electrical spiking activity.

1826 THE EFFECTS OF VIP ON INTESTINAL MOTILITY: STUDY ON EX VIVO PERFUSED ISOLATED CANINE JEJUNAL LOOPS. (Eng.) Kachelhoffer, J.; Mendel, C.; Dauchel, J.; Hohmatter, D.; Grenier, J. F. (U-61 Inserm, Avenue Moliere, 67200 Strasbourg Hautepierre, France). *Am. J. Dig. Dis.* 21(11):957-962; 1976.

The effects of vasoactive intestinal peptide (VIP) on intestinal motility were studied in isolated canine jejunal loops *ex vivo* perfused at normothermia under pulsatile flow with heparinized, oxygenated, and nonrecirculated canine whole blood, by means of an intraluminal balloon. VIP was administered intra-arterially either by 1-min injections or by 10-min infusions. For arterial concentrations of the polypeptide ranging between 25 pg/ml and 300-500 pg/ml, a fast but temporary relaxant effect was observed. For higher concentrations, VIP usually produced a biphasic response. The relaxant effect was followed by an increase of the basal muscular tone, often accompanied, for concentrations greater than 25 ng/ml, by a marked and transient increase in amplitude of the intestinal rhythmic contractions. During extended infusions, a biphasic response was also observed, but both effects were of short duration. A cholinergic origin of the secondary contracting phase was expected, but could not be demonstrated because, at blood concentrations at which atropine affected the biphasic response (10 μg/ml blood), not only was the contractile effect abolished, but the initial relaxing phase was abolished as well. It is suggested that the secondary contraction may be a "rebound excitation" of myogenic nature or a result of noncholinergic excitatory fiber stimulations. The short-term relaxant effect observed under the present conditions, even during long-time infusion of the polypeptide, fails to support an important physiological role of VIP as an hormonal inhibitor of intestinal motility. The biphasic response, however, might have a physiological significance as far as the aboral propulsion of the intestinal content requires a muscular inhibition that rapidly changes to contraction.

1827 ALTERED SMALL BOWEL PROPULSION ASSOCIATED WITH PARASITISM. (Eng.) Castro, G. A.; Badial-Aceves, F.; Smith, J. W.; Dudrick, S. J.; Weisbrodt, N. W. (Univ. Texas Medical Sch., Houston, TX). *Gastroenterology* 71(4):620-625; 1976.

Experiments were carried out in Sprague-Dawley rats to test the hypothesis that alterations of intestinal motility accompany enteric helminth infections. Motility was measured during the intestinal phase of infection with *Trichinella spiralis* by following the transit of radioactive chromium through the gut. Intraduodenal catheters were surgically implanted in rats. One week after the operation, one group of animals was infected with 8 x 10^3 *T. spiralis* larvae, and a second group was infected with 16 x 10^3 larvae. A third group of uninfected rats served as controls. $Na_2{}^{51}CrO_4$ was injected through the catheter into the duodenum of fasted animals 3, 4, or 5 days postinfection, and its propulsion through the small bowel was allowed to progress for 15 min. The distribution of radioactivity throughout the small intestine and cecum was then plotted as a func tion of gut length. Intestinal transit was increased significantly by infection. The leading edge of radioactivity traversed 100% of the gut length in infected rats and 70% in controls. The amount of injected radioactivity traversing the midpoint of the small intestine was estimated by regression equations to be 38% of the injected dose for control rats and 59 and 57% for infected groups, resp. Increased propulsive activity in parasitized rats was associated with inflammatory changes and a significant reduction in disaccharidase levels in the gut mucosa. The latter conditions were most marked in the proximal small bowel where the majority of worms resided.

1828 RELATIONSHIP OF CERVICAL AND ABDOMINAL VAGAL ACTIVITY TO LOWER ESOPHAGEAL SPHINCTER FUNCTION. (Eng.) Matarazzo, S. A.; Snape, W. J., Jr.; Ryan, J. P.; Cohen, S. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 71(6):999-1003; 1976.

The effects of electrical stimulation of the abdominal and cervical portions of the vagus on lower esophageal sphincter (LES) pressure were compared in 30 anesthetized opossums. Unilateral or bilateral abdominal vagotomy gave no significant change in basal LES pressure or in the sphincteric response to swallowing. Electrical stimulation of the peripheral end of the sectioned cervical vagus gave a frequency-related decrease in LES pressure, with a maximum reduction of 93.5 ± 2.5% at 10 Hz, 10 V. Stimulation of the central end of the cervical vagus increased LES pressure, with a maximum response of 34.0 ± 1.9 mm Hg. Neither peripheral nor central stimulation of the sectioned abdominal vagus had significant effect on LES pressure ($p>0.05$). LES relaxation in response to swallowing or cervical vagal stimulation was intact after bilateral abdominal vagotomy. These studies suggest that whereas the cervical portion of the vagus mediates inhibitory and excitatory changes in LES pressure, the abdominal vagus has no role in the control of LES function.

1829 LOWER ESOPHAGEAL SPHINCTER RESPONSE TO ORAL ADMINISTRATION OF CIMETIDINE IN NORMAL SUBJECTS. (Eng.) Freeland, G. R.; Higgs, R. H.; Castell, D. O. (Naval Regional Medical Center, Philadelphia, PA). *Gastroenterology* 72(1):28-30; 1977.

The effect of cimetidine on lower esophageal sphincter (LES) pressure was studied in eight healthy subjects, who received placebo or p.o. doses of cimetidine (50, 100, 200, and 400 mg) in a random, blind manner. Significant serum levels were achieved with all doses of cimetidine (50 mg=0.17 μg/ml, 100 mg=0.33 μg/ml, 200 mg=0.76 μg/ml, and 400 mg=1.61 μg/ml), indicating adequate absorption. Although these serum levels have been found to produce marked inhibition of gastric acid secretion, no discernible effect was found on LES pressure when compared to placebo. Cimetidine does not increase or decrease LES pressure, and is therefore not contraindicated in patients with reflux esophagitis.

1830 EFFECT OF MOTILIN ON THE LOWER OESOPHAGEAL SPHINCTER. (Eng.) Meissner, A. J.; Bowes, K. L.; Zwick, R.; Daniel, E. E. (Dept. Surgery, Inst. Hematology, Warsaw, Poland). *Gut* 17(12):925-932; 1976.

The effect of motilin on lower esophageal sphincter (LES) pressure was studied in unanesthetized dogs by using an infusion manometric technique. Motilin (0.009, 0.012, 0.025, and 0.05 μg/kg) administered as an i.v. bolus, produced statistically significant increases in resting LES pressure ($p<0.02$), which ranged from 35 and 40 cm water at the lowest dose to more than 75 cm at 0.05 μg/kg. Repetitive contractions of the LES appeared at doses as low as 0.009 μg/kg and increased from 12.3 ± 3.12 to 29.6 ± 2.10 contractions/10 min at doses of 0.012 and 0.5 μg/kg, resp. Stomach contractions over this dose range increased from 5.1 ± 1.72 to 17.5 ± 2.01 contractions, resp., over a 10-min period. Atropine (30 μg/kg, i.v.) caused a statistically significant decrease in the resting LES pressure ($p<0.001$); however, despite the administration of atropine, significant increases in LES pressure ($p<0.05$) were observed after the administration of ≥ 0.1 μg/kg motilin, and these increases reached a maximum of about 30 cm. Methacholine bromide (12 μg/kg) had no effect when given after atropine, but produced marked increases in LES pressure in the absence of atropine. After hexamethonium (2 mg/kg, i.v.) administration, the effects of motilin (0.2 μg/kg) on resting LES pressure were reduced, as they were after atropine; however, a slight but significant rise in LES pressure was observed, which reached a maximum of about 80 cm in comparison with a maximum of about 140 cm for motilin only. Hexamethonium (2 mg/kg) and atropine (30 μg/kg) together completely abolished the LES response to motilin. It is concluded that motilin increases LES pressure by acting on preganglionic cholinergic neurons to release acetycholine, which excites other cholinergic neurons supplying the circular muscle of the LES.

1831 LOWER ESOPHAGEAL SPHINCTER PRESSURE AND SERUM MOTILIN LEVELS. (Eng.) Eckardt, V.; Grace, N. D. (Lemuel Shattuck Hosp., 170 Morton St., Boston, MA 12130). *Am. J. Dig. Dis.* 21(12): 1008-1019; 1976.

Experiments were carried out in 13 healthy subjects to examine the effect of gastric alkalinization on lower esophageal sphincter (LES) pressure and serum motilin levels and to investigate a possible correlation between fasting serum motilin levels and LES pressure. During alkalinization by the 20-min intragastric instillation of 0.1 N $NaHCO_3$ the mean LES pressure increased significantly over the basal level, reaching its highest level during the last 5 min of gastric perfusion (31.8 ± 5.7 mm Hg versus 18.7± 2.7 mm Hg basal level, $p<0.01$). Gastric alkalinization did not affect the serum motilin levels. The lack of a correlation between resting sphincter pressure and fasting serum motilin levels supplies further evidence against a physiological role for motilin in the determination of LES strength.

1832 RESPONSES OF THE COMPETENT AND INCOMPETENT LOWER OESOPHAGEAL SPHINCTER TO PENTAGASTRIN AND ABDOMINAL COMPRESSION. (Eng.) Kaye, M. D.; Rein, R.; Johnson, W. P.; Showalter, J. P. (C321 Given Medical Bldg., Univ. Vermont, Coll. Medicine, Burlington, VT 05401). *Gut* 17(12):933-939; 1976.

The effects of continuous i.v. pentagastrin (PEN) infusion (0.45-9.0 μg/kg/hr) and/or intra-abdominal pressure on lower esophageal sphincter (LES) pressure were studied in 10 normal healthy subjects and in 10 patients with reflux esophagitis. Pressures were measured both by sensors stationary within the LES and by repeated withdrawal of the sensors from the stomach to the esophagus. Using the stationary catheter method, significant rises in pressure occurred in the normal subjects at a PEN dose of 0.9 μg/kg/hr; the peak response, which represented a 114% increase over the basal value, occurred at a dose of 4.5 μg/kg/hr PEN. In the patient group, only the 4.5 and 9.0 μg/kg/hr doses had a significant effect on LES pressure; the maximal increase of 62% over the basal value occurred at 9 μg/kg/hr. Using the continuous pullthrough method of pressure measurement, the results were similar; a peak response of 69% occurred in normal subjects at a PEN dose of 4.5 μg/kg/hr, whereas rises in LES pressure in patients, which occurred at PEN doses of 1.8, 4.5, and 9 μg/kg/hr, were not statistically significant. Rises in intragastric pressure during inflation of an abdominal cuff at 15 mm Hg were 4.42 ± 2.09 and 5.33 ± 2.05 mm Hg in controls and patients, resp., when measured by the stationary catheter method, and 3.99 ± 1.80 and 5.70 ± 2.80 mm Hg in controls and patients, resp., when measured by continuous pullthrough. During inflation to 30 mm Hg, stationary catheter pressure measurements were 9.32 ± 3.13 and 9.92 ± 3.60 mm Hg for controls and patients, resp.; the corresponding values measured by the continuous pullthrough method were 8.41 ± 3.15 and 9.84 ± 3.69 mm Hg, resp. The difference between controls and patients was significant ($p<0.02$) at 15 mm Hg when measured by stationary catheter, and was significant at 15 and 30 mm Hg ($p<0.05$) when measured by the continuous pullthrough method. Increases in LES pressure did not significantly exceed increases in intragastric pressure in either patients or normal subjects when measured by either method at all PEN doses used. Hence, there was no evidence of synergism between the effects of PEN and abdominal compression on the LES. It is inferred that gastrin does play a modest role in the physiological regulation of human LES tone. Relative insensitivity of the incompetent LES to PEN is believed to represent sphincteric muscle failure.

1833 DISTRIBUTION OF EXCITATORY VAGAL FIBERS IN CANINE GASTRIC WALL TO CONTROL MOTILITY. (Eng.) Daniel, E. E.; Sarna, S. K. (Dept. Neurosciences, Surgery, and Electrical Engineering, McMaster Univ., Hamilton, Ontario, Canada). *Gastroenterology* 71(4):608-613; 1976.

Patterns of electrical and mechanical responses in the gastric walls of anesthetized dogs to electrical stimulation (5-15 V, 6-20 Hz, 5 msec) of the anterior and posterior branches of the nerve of Latarjet and to local arterial drug perfusions on the two sides were studied. Electrical stimulation of the anterior nerve of Latarjet produced contractile activity on the anterior side, followed rapidly by activity on the posterior side and vice versa, indicating that the axons of the neurons from each side crossed over to the other side. This was not due to the propagation or conduction of electrical response activity, because electrical response activity and contractions induced locally by acetylcholine (0.1-5 μg), injected into a small artery supplying a segment of the stomach, did not propagate. The cross-over innervation and the direct innervation were both segmental in that the response to nerve stimulation dropped out in segments as the branches of the nerves of Latarjet were cut successively. Mainly, preganglionic axons crossed over from the anterior side to the posterior side, but both pre- and postganglionic axons crossed over from the posterior side. This was demonstrated by observing the spread of electrical and mechanical responses, or lack of it, in response to local injection of acetylcholine (2-3 μg) and dimethylpeprazinium (DMPP, 100-1,000 μg). For anterior nerve stimulation, the mean percent reduction in response on the anterior side was 6.8% after local DMPP perfusion on the posterior side and 72.1% after DMPP perfusion on the anterior side; the corresponding reductions in response on the posterior side after DMPP perfusion on the posterior or anterior side were 84.3% and 16.1%, resp. For posterior nerve stimulation, DMPP perfusion on the posterior versus anterior side resulted in reductions in response on the anterior side of 56.5% and 53.6%, resp., and in reductions in response on the posterior side of 72.5 and 8.2%, resp. These results indicate that there is a segmental distribution of excitatory neurons in the gastric wall, which is capable of producing a ring of contraction for controlling gastric emptying and mixing.

1871 PROPERTIES OF GASTRIC ANTRUM. III. SELECTIVITY AND MODIFICATION OF SHUNT CONDUCTANCE. (Eng.) Bajaj, S. C.; Spenney, J. G.; Sachs, G. (Lab. Membrane Biology, Univ. Alabama, Birmingham, AL 35294). *Gastroenterology* 72(1):72-77; 1977.

The permselectivity of the paracellular pathway of *Necturus* and bullfrog antrum was investigated with respect to intracationic selectivity and the K^+ and Cl^- permeability ratio as a function of mucosal pH. The intracationic selectivity sequence was $Rb^+ > K^+ > Cs^+ > Li^+$. Both antra showed weak cationic selectivity at pH 7.4, and at pH 4.4 for bullfrog and pH 3.0 for *Necturus*, the ratio P_{K^+}/P_{Cl^-} was unity. At lower mucosal pH, the tissues were anion selective. Treatment of the tissue with a water-soluble carbodiimide enhanced anion selectivity at higher pH; 10 mM carbenoxolone resulted in maintained cation selectivity at lower pH. These data suggest that carboxyl groups play a role in determining shunt selectivity; the increase in anion selectivity below pH 2.0 suggests that phosphat or sulfate groups could also be involved.

1872 LOCALIZATION OF GASTRIC INHIBITORY POLYPEPTIDE RELEASE BY INTESTINAL GLUCOSE PERFUSION IN MAN. (Eng.) Thomas, F. B.; Shook, D. F.; O'Dorisio, T. M.; Cataland, S.; Mekhjian, H. S.;

aldwell, J. H.; Mazzaferri, E. L. (Ohio State Univ. osp., 410 West 10th Ave., Columbus, OH 43210). *astroenterology* 72(1):49-54; 1977.

o determine the site of endogenous release of gas- ric inhibitory polypeptide (GIP), glucose perfusions 556 mM) of duodenum, proximal jejunum, mid-jejunum, nd ileum were performed in 19 human volunteers using n occluding balloon perfusion technique. Preper- usion GIP concentrations were below assay sens- tivity (125 pg/ml) in all subjects. After glucose erfusion, maximal serum GIP concentrations for he four groups were: duodenum, 1,383 ± 152 g/ml; proximal jejunum, 904 ± 87 pg/ml; mid- ejunum, 545 ± 91 pg/ml; and ileum 305 ± 38 pg/ml. ntegrated GIP secretion was significantly greater ith duodenal perfusion (111 ± 21 ng/min/ml) and roximal jejunal perfusion (69 ± 5 ng/min/ml) than ith either mid-jejunal (47 ± 7 ng/min/ml) or ileal 25 ± 6 ng/min/ml) perfusions. Peak serum insulin oncentrations and integrated insulin secretion were lso significantly greater with perfusion of the uodenum or proximal jejunum. Serum glucose concen- rations, integrated serum glucose, and glucose bsorption were similar for the four areas perfused. he results indicate that the proximal small ntestine is the primary site of endogenous GIP elease in man, but that smaller quantities are also eleased by the distal small bowel.

373 RELEASE OF IMMUNOREACTIVE SEROTONIN FOLLOWING ACID PERFUSION OF THE DUODENUM. (Eng.) ellum, J. M., Jr.; Jaffe, B. M. (146th Station Hosp., PO, New York, NY 05055). *Ann. Surg.* 184(5):633-636; 976.

recently developed radioimmunoassay was used o demonstrate the release of serotonin following cidification of the duodenum in dogs. Cannulas ere placed in the portal vein, hepatic vein, and nfrarenal vena cava in eight anesthetized dogs. The uodenum of each dog was irrigated with saline (con- rol) and 0.1 N HCl (50 ml/10 min). Heparinized lood samples were taken from each cannula 5 min efore, and 1, 5, 10, 30, and 60 min after each rrigation, for measurement of immunoreactive sero- onin concentrations. Serotonin concentrations did ot change during saline irrigation of the duodenum. n contrast, serotonin release was consistently ob- erved after duodenal acidification (pH 1.5-2.0). ortal venous serotonin concentrations were increased t 1 min (356 ± 147 ng/ml) and following a biphasic attern remained elevated at 30 and 60 min (499 ± 131 nd 489 ± 187 ng/ml, resp.) Concentrations in the epatic vein rose more slowly and to a lower peak 357 ± 123 ng/ml at 10 min). Caval serotonin concen- rations were increased at 10 min (342 ± 121 ng/ml), ut promptly returned to baseline levels. In the astrointestinal tract, immunoreactive serotonin oncentrations were highest in the duodenal bulb 15.4 µg/g). This study demonstrates that some of the erotonin released after acid perfusion escapes he- atic inactivation. The findings support the possibil- ty that serotonin may be a gastrointestinal hormone nvolved in the feedback inhibition of gastric acid ecretion.

1874 EFFECT OF GASTRIC HYPERSECRETION ON THE CANINE DUODENUM. (Eng.) Henriksen, F. W.; Gammeltoft, M.; Rune, S. J. (Inst. Experimental Res. in Surgery, Univ. Copenhagen, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(6):609-614; 1976.

The possibility that chronic gastric hypersecretion injures the duodenal mucosa and thereby reduces the capability of the duodenum to neutralize acid was investigated in dogs. Gastric hypersecretion was produced for 3 weeks in three dogs by the daily injection of a gastrin preparation with a prolonged effect. After an s.c. injection of tetragastrin (1.5 mg), given together with a test meal, the acidity of both gastric and duodenal contents increased significantly, the pH being 2-3 units lower than when the meal was given alone. After the 3 weeks of gastric hypersecretion, the pancreatic bicarbonate response to exogenous secretin was unchanged, while the bicarbonate response to duodenal acidification was decreased from 2.03 mEq/30 min to 1.27 mEq/30 min ($p<0.05$); this was compatible with an impaired secretin release. Also, the concentration of lactase, maltase, sucrase, and alkaline phosphatase in mucosal biopsies from the second part of the duodenum was significantly reduced ($p<0.001$). These results indicate that gastric hypersecretion causes mucosal damage in the duodenum and thereby reduces the release of secretin.

1875 INFLUENCE OF ACID SECRETORY STATE ON THE GASTRIC MUCOSAL TOLERANCE TO BACK DIFFUSION OF H^+. (Eng.) O'Brien, P.; Silen, W. (Dept. Surgery, Harvard Medical Sch., Boston, MA). *Gastroenterology* 71(5):760-765; 1976.

The effects of back diffusion of hydrogen ions (H^+) on the potential difference (PD), electrical resistance (R), and short circuit current (I) of spontaneously secreting and burimamide-inhibited bullfrog gastric mucosae were studied *in vitro*. When back diffusion of H^+ was induced by the passage of 510 µamperes (µA)/cm^2 of electrical current from the secretory side (S; pH 2.25) to the nutrient side (N: pH 7.20) for 30 min, spontaneously secreting mucosae showed significant decreases in PD (-23.6 ± 1.0 to -16.2 ± 2.1 mV, $p<0.005$), and I (80 ± 5 to 61 ± 7 µA/cm^2, $p<0.025$); no significant change occurred in R. When mucosae were inhibited with burimamide (4 mM), significant decreases were seen in PD (-26.8 ± 1.5 to -3.4 ± 1.4 mV, $p<0.001$), I (50 ± 5 to 13 ± 5 µA/cm^2, $p<0.001$), and in R (473 ± 55 to 170 ± 32 ohms/cm^2, $p<0.001$). Stimulation of the mucosae with histamine (4×10^{-4} M) after inhibition by burimamide produced responses to the passage of current that were similar to those observed in spontaneously secreting tissue. When back diffusion of H^+ was induced by establishing a concentration gradient of H^+ from S to N or by exposing the secretory surface to sodium taurocholate (10 mM) with a secretory pH of 2.25, burimamide-inhibited tissue demonstrated significantly greater depressions in PD (-29.8 ± 2.6 to -8.4 ± 3.3 mV, $p<0.001$), R (346 ± 53 to 122 ± 24 ohms/cm^2, $p<0.001$), and in I (71 ± 12 to 25 ± 7 µA/cm^2, $p<0.001$), in comparison with spontaneously secreting tissue, which showed insignificant changes in R and I and a drop in PD from -26.7 ± 1.8 to -17.4 ± 4.4 mV ($p<0.05$). Intracellular pH was significantly higher (7.28 ± 0.02) in spontaneously secreting tissue stimulated by histamine (4×10^{-4} M) than in tissue (7.11 ± 0.03) inhibited by metiamide (2 mM). These results suggest that the secretory status of the mucosa, and hence its acid-base status, are important determinants in the tolerance of the tissue to exogenous back diffusion of H^+. The measure of absolute loss of H^+ from the mucosal solution alone may not be an adequate assessment of the gastric mucosal barrier.

1876 EFFECT OF CHRONIC ANTACID INGESTION ON SERUM GASTRIN AND GASTRIC SECRETION.

(Eng.) Caldwell, J. H.; Cline, C. T.; Fox, A. W.; Cataland, S. (Univ. Hosp., 410 West 10th Ave., Columbus, OH 43210). *Am. J. Dig. Dis.* 21(10):863-866; 1976.

The effects of chronic antacid ingestion on fasting serum gastrin and basal and stimulated acid secretion were investigated in 20 healthy subjects to assess whether antacid therapy of peptic ulcer might account for gastrin cell hyperplasia, altered gastrin inhibition by acid, and gastric hypersecretion. Ten subjects ingested 30 ml of aluminum-magnesium hydroxide suspension 4 times daily for 6 weeks. Ten subjects received the same dose of aluminum-magnesium hydroxide plus calcium carbonate (15 ml) 4 times daily for 6 weeks. All subjects plus five untreated controls were examined before and after treatment. After 6 weeks of antacid therapy, neither group showed significant changes in fasting serum gastrin, basal or maximal histamine-stimulated acid, or acid output in response to a protein meal, when compared with the control group or with their prestudy values. The results suggest that normal subjects do not acquire functional hyperactivity of the gastrin mechanism after a period of regular antacid use.

1877 GASTRIC MUCOSAL LESIONS PRODUCED BY INTRAVENOUS INFUSION OF ASPIRIN IN CATS.

(Eng.) Bugat, R.; Thompson, M. R.; Aures, D.; Grossman, M. I. (Centre Claudius Regard, Toulouse, France). *Gastroenterology* 71(5):754-759; 1976.

The lesions produced by the i.v. infusion of aspirin in cats were characterized, and the question of whether these lesions are accompanied by the changes that are commonly used as an index of a "broken barrier" was investigated. Aspirin (25-200 mg/kg/day) was given by continuous i.v. infusion to 35 intact cats for 7 days. Gastric mucosal lesions occurred in 50-70% of the animals in the various dosage groups, including deep ulcers in 20%. All ulcers were in antral mucosa near its border with the oxyntic mucosa. The incidence of lesions, including ulcers, showed no apparent relation to the dose of aspirin. With all but the highest dose, plasma salicylate levels were within or below what is regarded as the therapeutic range for man. Aspirin (100 mg/kg/day) was given for 7 days to four cats with pouches containing all of the antral mucosa plus some oxyntic mucosa. One or more deep ulcers occurred in the antral mucosa of the pouches in each of these animals. The electrical potential difference across the mucosa did not decrease, and net fluxes of hydrogen ions out of the pouch and of sodium ions into the pouch did not increase during the 7 days of aspirin administration, despite the occurrence of ulcers in the pouches. It is concluded that i.v. aspirin, in doses giving plasma levels within or below the therapeutic range for man, causes gastric mucosal lesions, including deep ulcers within 7 days in cats. These lesions occur without the changes in electrical potential difference or hydrogen and sodium fluxes that are regarded as characteristic of the "broken barrier."

1878 MECHANISM OF PREVENTION OF ASPIRIN-INDUCED GASTRIC LESIONS BY BILE DUCT LIGATION IN THE RAT.

(Eng.) Guth, P. H.; Paulsen, G.; Lynn, D.; Aures, D. (Wadsworth Veterans Admin. Hosp., Los Angeles, CA 90073). *Gastroenterology* 71(5):750-753; 1976.

Studies were carried out in male Sprague-Dawley rats to determine whether bile duct ligation or pylorus ligation inhibits aspirin-induced gastric lesions, and, if so, what the protective mechanisms are. Aspirin (200 mg/kg) was instilled into the stomachs of ether-anesthetized rats 0.5 hr after bile duct ligation or pylorus ligation. Four hours later, the rats were killed, the stomachs were examined, and mucosal lesions were scored. Bile duct ligation, but not pylorus ligation, significantly protected against aspirin-induced gastric lesions. Bile duct ligation in pylorus-ligated rats inhibited gastric acid output by 78%. Instilling HCl plus aspirin in bile duct-ligated rats restored lesion formation. Shunting bile to the colon (to prevent bile reflux) did not prevent aspirin lesions. Salicylate determination to ascertain whether bile duct ligation altered aspirin absorption revealed no significant differences between bile duct ligation and aspirin, shunt and aspirin, and sham shunt and aspirin in plasma and gastric tissue salicylate concentrations. Bile duct ligation protects against aspirin-induced gastric mucosal lesions by inhibiting gastric HCl secretion. As a corollary, a certain amount of acid in the stomach is necessary for aspirin-induced gastric lesions to form. Bile reflux is not necessary for aspirin-induced gastric lesions in the rat.

1879 SALICYLATE- AND ASPIRIN-INDUCED UNCOUPLING OF OXIDATIVE PHOSPHORYLATION IN MITOCHONDRIA ISOLATED FROM THE MUCOSAL MEMBRANE OF THE STOMACH.

(Eng.) Jorgensen, T. G.; Weis-Fogh, U. S.; Nie sen, H. H.; Olesen, H. P. (Gardeniavej 15, DK-2970 Horsholm, Denmark). *Scand. J. Clin. Lab. Invest.* 36(7):649-654; 1976.

The ability of salicylate and acetylsalicylate to induce uncoupling of oxidative phosphorylation in mitochondria isolated from gastric mucosa was tested to evaluate the hypothesis that salicylic acid and its derivatives damage mucosal membranes by disrupting

rocesses dependent upon the rate of oxidative phos-
iorylation, such as mucous and acid secretion and
embrane permeability. Oxidative phosphorylation in
.tochondria from the corpus gland area of miniature
.gs was assayed *in vitro* by: oxygen consumed during
ie phosphorylation of ADP to ATP, the respiratory
ontrol ratio (RCR) or the rate of respiration prior
and following the phosphorylation of ADP, and the
iximum respiratory capacity. Salicylate, applied
concentrations of 0.7-5.6 mM, produced a significant
icrease in the respiratory rate and a corresponding
ecrease in RCR at 0.7 mM, while the phosphate:oxygen
itio was significantly decreased at 1.4 mM. Uncoup-
ing of oxidative phosphorylation was observed at con-
entrations of 3.5-5.6 mM. Statistically equiva-
ent effects were observed in each of these parameters
.th acetylsalicylate, thus proving that salicylic
id and its derivatives are capable of uncoupling
idative phosphorylation *in vitro* in mitochondria
olated from gastric mucosae.

80 EFFECTS OF CARBENOXOLONE ON GASTRIC MUCOSAL PERMEABILITY AND BLOOD FLOW IN THE DOG.

Eng.) Simons, M. A.; Moody, F. G.; Torma, M. J.
Dept. Surgery, Univ. Utah Sch. Medicine, Salt Lake
ity, UT). *Gastroenterology* 71(4):603-607; 1976.

ie effects of carbenoxolone on canine gastric corpus
ere examined at neutral and acidic pH in an attempt
resolve conflicting evidence concerning its influ-
ice upon mucosal permeability and gross ulceration.
ie low solubility of the drug at low pH suggested
iat more consistent and effective concentrations
ight be obtained at a higher pH. Application of
.25% carbenoxolone (pH 7.5-8.0) to the mucosal
irface resulted in a significant drop in the gas-
ric potential difference of 56 ± 2 mV and a large
lux of hydrogen ions out of the lumen. In contrast,
reatment with the drug suspended in 0.15 N HCl
roduced only minimal changes in the potential dif-
erence and hydrogen ion flux. Subsequent exposure
the mucosae treated with either acidified or neu-
ral solutions of carbenoxolone to 20 mM aspirin
roduced an increase in hydrogen ion back-diffusion
imilar to that observed in the control treated with
spirin alone. Replacing a neutral solution of
arbenoxolone by isotonic HCl produced a rise
the blood flow, which was much higher than that
oserved in the control (p<0.05). Topical carben-
olone at neutral pH appears to be effective for
icreasing gastric permeability. However, no appar-
it immediate protection against aspirin was observed.
ie authors suggest that long-term protection by
arbenoxolone against ulcers may derive from in-
reased stimulation of mucous secretion.

81 EFFECT OF CIMETIDINE ON GASTRIC MUCOSAL HISTAMINE AND HISTIDINE DECARBOXYLASE AC-
VITY IN RATS.

(Eng.) Maslinski, S.; Sewing, K. F.;
Dept. Pharmacology, Univ. Tubingen, Tubingen, W. Ger-
igestion 15(2):121-128; 1977.

ie effects of low and high doses of cimetidine, ad-
inistered in the presence and absence of pentagas-
rin, upon histamine concentration in the gastric
icosae and histidine decarboxylase activity were
studied in both conscious and anesthetized gastric fistula rats. A single injection of pentagastrin (250 μg/kg) in conscious rats caused a decrease in the mucosal histamine concentration ($p<0.005$) and an increase in histidine decarboxylase activity ($p<0.001$). Administration of cimetidine (5 mg/kg) in a dose low enough to inhibit gastric secretion in anesthetized rats did not interfere with these effects. A high dose of cimetidine (50 mg/kg) produced the same effects upon histamine concentration and histidine decarboxylase activity as pentagastrin. Apparently, cimetidine can inhibit pentagastrin-stimulated gastric acid secretion without affecting histidine decarboxylase activity. Less pronounced effects of cimetidine on anesthetized rats were observed, except in the presence of high doses of cimetidine, when the stomach was perfused with 0.05 N HCl. HCl significantly elevated both the histamine concentration and the histidine decarboxylase activity. This eliminated the possibility that the stimulatory effect of high doses of cimetidine on histidine decarboxylase activity is caused by endogenous gastrin released in response to increased antral pH, which results from lack of gastric acid secretion. The increased activity may be due to an attempt to override the sustained inhibition of gastric secretion by cimetidine.

1882 EFFECT OF THE HISTAMINE H_2-RECEPTOR ANTAGONIST, CIMETIDINE, ON GASTRIC SECRETION AND SERUM GASTRIN DURING INSULIN INFUSION IN MAN.

(Eng.) Carter, D. C.; Forrest, J. A. H.; Logan, R. A.; Ansell, I.; Lidgard, G.; Heading, R. C.; Shearman, D. J. C. (Royal Infirmary, Edinburgh EH3 9YW, Scotland). *Scand. J. Gastroenterol.* 11(6):565-570; 1976.

The effect of cimetidine infusion (100 mg/hr) on the acid secretory response to insulin infusion (0.03 U/kg/hr) was tested in six healthy male volunteers. Although no difference in pepsin secretion or serum gastrin concentration was observed between volunteers and controls, the volume (74.3 ml/hr in treated subjects, 156 ml/hr in controls) and concentration (4.36 versus 17.73 mmol/hr) of acid output were significantly decreased. In an extended test on three subjects, both acid secretion and total pepsin output were significantly reduced. Cimetidine, a nontoxic analog of metiamide, is proposed as a potentially useful agent in treatment of peptic ulcer diathesis.

1883 ADENYLATE CYCLASE OF THE DOG GASTRIC MUCOSA: STIMULATION BY HISTAMINE AND INHIBITION BY METIAMIDE.

(Eng.) Ruoff, H. J.; Sewing, K. F. (Pharmakologisches Institut der Universitat Tubingen, Wilhelmstrasse 56, D-7400 Tubingen, W. Germany). *Naunyn-Schmiedeberg's Arch. Pharmacol.* 294(2):207-208; 1976.

Experiments were carried out to determine whether histamine activates gastric mucosal adenylate cyclase (AC) in the dog, as it does in rodents. The activity of the nonstimulated, basal AC was reduced 27% and 38% by the histamine H_2-receptor antagonist metiamide in concentrations of 10^{-8} M and 10^{-6} M, resp. ($p<0.025$ and $p<0.001$, resp.). The histamine H_1-receptor antagonist mepyramine at the same concentrations had no effect on basal AC activity. Histamine (5 x 10^{-6} M) stimulated basal AC activity by 20% ($p<0.01$). In the presence of 10^{-5} M metiamide, a concentration-dependent stimulation of the enzyme by histamine was observed. The data indicate that endogenous histamine in dog gastric mucosal homogenate contributes at least in part to basal AC activity. This effect is mediated by H_2 excitation.

1884 EFFECT OF PARACETAMOL (ACETAMINOPHEN) ON GASTRIC IONIC FLUXES AND POTENTIAL DIFFERENCE IN MAN. (Eng.) Ivey, K. J.; Settree, P. (Univ. Missouri Medical Center, Columbia, MO 65201). *Gut* 17(11):916-919; 1976.

The effect of large doses of paracetamol (2.0 g) on gastric ionic fluxes was studied in five healthy subjects, and its effect on gastric potential difference was compared with that of 600 mg aspirin. In contrast with salicylates, paracetamol caused no significant alteration in the movement of H+ and Na+ ions over control periods. Aspirin causes a significant fall in transmucosal potential difference (PD) across gastric mucosa of 15 mV, while paracetamol caused no significant change. Four times the recommended dose of paracetamol does not alter gastric ionic fluxes or potential difference. These studies support the choice of paracetamol over aspirin as an analgesic, where damage to gastric mucosa may be critical.

1885 FAILURE OF PENTAGASTRIN ADMINISTRATION TO RESTORE POSTPRANDIAL ACID SECRETION FROM HEIDENHAIN POUCHES AFTER ANTRECTOMY IN DOGS. (Eng.) Keuppens, F.; Bremen, J.; Woussen-Colle, M. C.; De Graef, J. (Dept. Surgery, Free Univ. Brussels, Brussels, Belgium). *Surgery* 80(5):586-590; 1976.

To elucidate the decrease in acid secretory response to feeding from Heidenhain pouches following antrectomy, acid outputs from the Heidenhain pouches of four dogs were measured in response to feeding boiled liver with or without the simultaneous administration of pentagastrin (0.125-16 μg/kg/hr). Antrectomy was performed, and the experiments were repeated. Antrectomy decreased the acid response to feeding by 90%. The pre-antrectomy response was restored by pentagastrin infusion, but near maximal doses were needed, and the maximal response to feeding plus pentagastrin could not be restored. These results indicate that the decrease of the acid secretory response to feeding from Heidenhain pouches after antrectomy cannot be explained fully through suppression of endogenous gastrin release. Antrectomy probably interferes with the intestinal phase of gastric secretion.

1886 INHIBITION OF GASTRIC ACID SECRETION BY SOMATOSTATIN AND ANALOGS IN THE RAT. (Eng.) Lippmann, W.; Borella, L. E. (Biochemical Pharmacology Dept., Ayerst Res. Lab., Montreal, Quebec, Canada). *Pharmacol. Res. Commun.* 8(5):445-454; 1976.

Inhibition of gastric acid secretion by somatostatin and its analogs was studied in unanesthetized male albino rats. Somatostatin (0.6 μM/kg, s.c.) caused a marked decrease in gastric acid output from 50-60 μEq/min to about 10-20 μEq/15 min for 60 min, with the output rate returning to the basal rate in a subsequent 30-min period. The overall duration of the inhibitory effect increased from 77 min at a dose of 0.6 μM/kg to 133 min at a dose of 2.0 μM/kg. The degree of inhibition of total acid output was 75 ± 3% for each dose. (Descarboxy^{14})-somatostatin and (desamino^{1})(descarboxy^{14})-somatostatin (0.6 μM/kg, s.c.) were less effective, with the inhibition of total acid output being 67 ± 3 and 62 ± 5%, resp., and the durations of the inhibitory effect being 38 ± 8 and 34 ± 3 min, resp. (Desamino^{1})-somatostatin (0.6 μM/kg, s.c.) was similar in activity to somatostatin and inhibited total acid output by 73 ± 4%, with the duration of inhibition being 87 ± 14 min. (D-lysine^{9})-somatostatin was not appreciably effective in inhibiting gastric acid secretion, even at a dose of 2 μM/kg (25% inhibition). Atropine (0.014 μM/kg, s.c.) was similar in activity to somatostatin and inhibited gastric acid output by 69 ± 5%, with the inhibition duration being 73 ± 8 min. In each of these cases, the onset of the inhibiting effect occurred 15 min after drug injection. Gastric acid output stimulation was induced by two consecutive equal doses of pentagastrin (50 μg/kg/hr, i.v. for 45 min) spaced 3-4 hr apart, with the values of gastric secretion after these two doses being 592 ± 94 and 882 ± 101 μEq, resp. However, somatostatin (0.05 μM/kg) caused maximal inhibition (86 ± 9%) of the induced secretion and the basal secretion (30 ± 10%). Thus, somatostatin and various analogs inhibit basal gastric acid secretion in the unanesthetized rats, and pentagastrin-induced gastric acid secretion is antagonized by somatostatin.

SECRETION AND METABOLISM

Pancreas

1926 MICROPUNCTURE STUDY OF PANCREATIC SECRETION IN THE CAT. (Eng.) Lightwood, R.; Reber, H. A. (Veterans Admin. Hosp., San Francisco, CA). *Gastroenterology* 72(1):61-66; 1977.

An *in vivo* model for micropuncture of the cat pancreas and data regarding the sites of water and electrolyte secretion in this preparation are presented. Fifty female mongrel cats were used. During maximal secretin stimulation (4-6 U/kg/hr), juice was collected from intralobular (10-50 μ diameter) and extralobular (25-300 μ diameter) ducts by micropuncture and compared with juice simultaneously collected from the main duct. The juice (Cl^-) steadily decreased from intralobular ducts (112 ± 9 mEq/l) to the main duct (46 ± 8 mEq/l). During *in vivo* perfusion, secretion of H_2O and HCO_3^- by the extralobular ducts (25-150 μ diameter) was sensitive to secretin. There was no evidence for secretion by the main duct. Pancreatic secretion of water and electrolytes appears to result from the admixture of a Cl-rich primary secretion originating from intralobular structures and a larger volume of HCO_3^--rich fluid originating from the smaller extralobular ducts. HCO_3^--Cl^- exchange in these ducts accounts for the characteristic changes in concentrations of HCO_3^- and Cl^- as the flow rate varies.

1927 DISTRIBUTION AND RELEASE OF HUMAN PANCREATIC POLYPEPTIDE. (Eng.) Adrian, T. E.; Bloom, S. R.; Bryant, M. G.; Polak, J. M.; Heitz, P.; Barnes, A. J. (Royal Postgraduate Medical Sch., London, England). *Gut* 17(12):940-944; 1976.

The distribution and release of human pancreatic polypeptide (HPP) were studied using a radioimmunoassay, which utilized antisera against HPP produced in rabbits. HPP distribution in the alimentary tract was investigated in three adult baboons and two monkeys that had been maintained in a human diet for several yr. Approximately 93% of the total pancreatic polypeptide (PP) in the gut was found in the pancreas. Small amounts of PP immunoreactivity were found throughout the intestinal tract, from the esophagus to the colon. An investigation of human apudomas (insulinomas, glucagonomas, gastrinomas, and VIPomas) revealed that the mean tumor PP content of neoplasms containing PP cells was 2,600 pM/g, as compared with 390 pM/g for normal human pancreas. The immunoreactive PP from these tumors and from normal pancreas was chromatographically indistinguishable from the pure peptide. The plasma concentration of PP in positive tumor cases was greater than 300 pM, as compared with a normal range of 2-90 pM. The mean fasting plasma HPP level of 25 normal subjects was 31.2 ± 6.2 pM; after a normal hospital lunch, the 30-min peak in postprandial plasma HPP was 164 ± 46.2 pM, and the plasma PP level 6 hr after the meal was still raised at 80.1 ± 26.6 pM. In fasting plasma from patients who had undergone total pancreatectomy, PP was undetectable (<6 pM). Since fasting plasma PP levels in patients with pancreatic endocrine tumors containing PP are higher than even the postprandial level in normal subjects, PP measurement is a useful diagnostic tool for cases of pancreatic endocrine tumors.

1928 MECHANISM OF PANCREATIC POLYPEPTIDE RELEASE IN MAN. (Eng.) Adrian, T. E.; Besterman, H. S.; Cooke, T. J. C.; Bloom, S. R.; Barnes, A. J.; Russell, R. C. G.; Faber, R. G. (Hammersmith Hosp., London W12 OHS, England). *Lancet* 1(8004):161-163; 1977.

To study the mechanism of pancreatic polypeptide (PP) release, the effects of vagotomy, hormone infusion, and i.v. nutrition were investigated. After a standard hospital lunch, the plasma PP concentration showed a rapid and identical rise in 10 healthy controls, 11 duodenal ulcer patients, and 6 postvagotomy patients, but remained undetectable in 4 totally pancreatectomized subjects. The plasma PP level was unaffected by the i.v. administration of glucose (20 g as 50% solution), amino acids (25 g), or fat (8 g). However, during the i.v. infusion of cerulein (100 ng/kg/hr, 40 min), the PP rose by nearly fivefold, and the injection of secretin (2 Crick-Harper-Raper U/kg, i.v.) produced an even greater rise (from 18 ± 3 pM to 264 ± 86 pM). In 19 duodenal ulcer patients, insulin hypoglycemia produced a rapid increase in plasma PP, but this did not occur in any of the 17 patients studied after truncal vagotomy. The results suggest that PP is released by p.o., but not i.v., nutrients, and the existence of an entero-PP axis is postulated. One component of this axis may be the vagal innervation, but the normal postprandial rise seen after vagotomy suggests that other control mechanisms, such as the intestinal hormones, are more important.

1929 QUANTITATION OF ACTIVE PANCREATIC ENDOPEPTIDASES IN THE INTESTINAL CONTENTS OF GERM-FREE AND CONVENTIONAL RATS. (Eng.) Genell, S.; Gustafsson, B. E.; Ohlsson, K. (Malmo General Hosp., S-21401 Malmo, Sweden). *Scand. J. Clin. Lab. Invest.* 36(6):757-762; 1976.

Trypsin, chymotrypsin, and elastase were measured in the intestinal contents of germ-free and conventional laboratory rats (Swedish AGUS strain). Concentrations of active trypsin were highest in the lower half of the small intestine in both germ-free and conventional rats, with the values being about 400 and 600 μg/g, resp. Activity fell abruptly in the cecal contents and was about 100 μg/g for both germ-free and conventional rats. Most striking was the relatively high amount of active trypsin in the feces of germ-free rats (over 100 μg/g), as compared with a negligible amount in the feces of conventional rats. Both types of rats showed about 200 μg/g of active trypsin in the upper small intestinal contents. Active chymotrypsin was easily demonstrable in the small intestine, but occurred only in very low concentrations in the cecal contents and feces; no certain differences existed between upper and lower small intestinal contents or between germ-free and conventional rats. Concentrations of active elastase were highest in the upper half of the small intestine in both germ-free and conventional rats, with the values being about 1,300 μg/g for germ-free rats and about 800 μg/g for conventional rats. Active elastase was also present in the cecal contents (about 150 μg/g) and feces (about 200 μg/g) of germ-free rats, but not in those of conventional rats. These results suggest that normal microbiological inhabitants of the intestinal tract of rats play a role in the inactivation of pancreatic enzymes.

1930 REQUIREMENTS FOR ACTIVATION OF TRYPSINOGEN AND CHYMOTRYPSINOGEN IN RABBIT PANCREATIC JUICE. (Eng.) Glazer, G.; Steer, M. L. (St. Mary's Hosp., Praed St., London W2, England). *Anal. Biochem.* 77(1):130-140; 1977.

Requirements for the activation of trypsinogen and chymotrypsinogen were studied in rabbit pancreatic juice. Trypsinogen was optimally activated by purified enterokinase at 30 C after 2 hr in the presence of 25 mM Tris-HCl (pH 8.1) containing 25 mM $CaCl_2$. Chymotrypsinogen was optimally activated by trypsin at 4 C after 2 hr in the presence of 50 mM Tris-HCl (pH 8.1). Bovine serum albumin was added to the activation mixtures to prevent loss of zymogens through adsorption to the container walls. The activation of trypsinogen by purified enterokinase varied with temperature, time, Ca^{2+} concentration, and enterokinase concentration; it was unchanged over the pH range of 7.4-8.8. Activation of chymotrypsinogen by trypsin was found to vary with temperature, time, and trypsin concentration, but was not altered by the presence or absence of Ca^{2+} and was unchanged over the same pH range. Using optimal conditions for zymogen activation, the eventual proteolytic activity and the amount of juice protein being activated were found to be directly related. Deviations from these conditions of activation could lead to erroneous results.

1931 CHRONIC ALCOHOLISM AND CANINE EXOCRINE PANCREAS SECRETION: A LONG TERM FOLLOW-UP STUDY. (Eng.) Sarles, H.; Tiscornia, O. M.; Palasciano, G. (Unite de Recherches de Pathologie Digestive, INSERM U-31, 46 chemin de la Gaye, 13009 Marseille, France). *Gastroenterology* 72(2):238-243; 1977.

Sequential changes in pancreatic secretion were evaluated during a 2- to 3-yr follow-up study in eight dogs provided with Thomas gastric and duodenal fistulas. Four animals received intragastric ethanol (2 g/kg) daily for 3 yr; four others served as controls. In alcohol-fed animals, flow rate and bicarbonate output in response to 1 clinical U/kg/hr of secretin were increased at the end of 2 yr, but not after 1 yr of alcohol feeding. At the end of 2 yr, the dose-response curve of pancreatic secretion to cholecystokinin was unchanged, but the maximal bicarbonate and water secretion in response to high doses of secretin was increased. These modifications may be explained by reduplication of pancreatic ducts secondary to the development of chronic pancreatitis, which was verified by biopsy. The previous report of an increased cholecystokinin release in the course of chronic alcohol consumption in dogs seems to be attributable to an artifact. The present study showed that the pancreatic response to intraduodenal oleic acid was not significantly modified by 3 yr of alcohol feeding.

1932 SHORT DATED INFLUENCE OF TEMOVAL [sic] OF THE EXOCRINE PANCREATIC SECRETION (ENZYMATIC OR TOTAL) UPON THE APPARENT DIGESTIBILITY OF A DIET, IN THE PIG [Abstract]. (Eng.) Corring, T.; Bourdon, D. (INRA, 78350 Jouy en Josas, France) *Scand. J. Gastroenterol.* 11(41):80; 1976.

SECRETION AND METABOLISM

Hepatobiliary Tract

1965 THE ROLE OF CHOLECYSTOKININ IN RADIOGRAPHIC OPACIFICATION OF THE GALLBLADDER. (Eng.) Herzog, R. J.; Nelson, J. A. (Univ. California Sch. Medicine, San Francisco, CA). *Invest. Radiol.* 11(5):440-448; 1976.

The effect of cholecystokinin (CCK) on hepatic elimination of i.v. iopanoate and on gallbladder opacification was studied in nonoperated dogs with intact enterohepatic circulation and normal endogenous bile salt pool. The i.v. administration of CCK (3 U/kg) resulted in a 32% increase in apparent transport maximum (maximum rate of elimination) or iopanoate and earlier and enhanced gallbladder opacification. This increase in apparent transport maximum was abolished by cholecystectomy, indicating that the increase was a result of the release of bile salts from the gallbladder rather than a direct effect of the hormone on the hepatic elimination of iopanoate. The early gallbladder opacification and increased density of contrast material in the gallbladder were related to CCK-induced emptying of the gallbladder and subsequent filling with opacified bile.

1966 INFLUENCE OF RETROGRADE VOLUME AND SHORT TIME CHOLESTASIS ON THE BILIARY REABSORPTION OF SULFOBROMOPHTHALEIN SODIUM (BSP) AND PHENOL 3, 6 DIBROMPHTHALEIN DISULFONATE (DBSP) FROM THE RA BILIARY TREE AFTER RETROGRADE INTRABILIARY INJECTI (RII). (Eng.) Dammann, H. G.; Essen, J. (Medizinische Klinik der Universitat Hamburg, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Res. Exp. Med. (Berl.)* 168(3):187-198; 1976.

The reabsorption of equimolar doses (1.2 µmol) of BSP and its analogue phenol 3,6-dibromphthalein disulfonate (DBSP) from the rat biliary tree was determined using the retrograde intrabiliary injec tion (RII) technique, and the influence of retrograde volume and short-time cholestasis on reabsorption was studied. RII was performed with a microliter syringe joined to a cannula positioned in the proximal third of the common bile duct. This technique guaranteed accurate administration of the volumes; also, free bile flow could be reinitiated 3-5 sec after RII. Bile samples were collected in 2.5-min intervals up to the fifth minute, in 5-min intervals up to 15 min, and at 30 min. No significant differences in the biliary reabsorption of BSP and DBSP after RII were detected. Increasing the retrograde volume from 20 to 40, 60, 110, and 160 µl led to decreased percentage recoveries in the bile in the first 2.5 min (88.0 ± 3.8-15.6 ± 3.1%), when bile flow was started immediately after RII. Increasing the duration of cholestasis (bile flow was started immediately, 0.5 min, 3 min, 6 min, and 30 min after RII) resulted in decreased percentage recoveries of BSP and DBSP during the first 2.5 min after free bile flow was reinitiated (52.7 ± 3.6-20.0 ± 1.2%). The amount of biliary BSP conjugate increased concommitantly with the duration of cholestasis, indicating that ductular-hepatocellular circulation continues even during complete common bile duct obstruction.

1967 THE DYNAMICS OF α-FETOPROTEIN AND ALBUMIN SYNTHESIS IN HUMAN AND RAT LIVER DURING NORMAL ONTOGENY. (Eng.) Nayak, N. C.; Mital, I. (All-India Inst. Medical Sciences, Ansari Nagar, New Delhi 110016, India). *Am. J. Pathol.* 86(2):359-371; 1977.

The dynamics of synthesis of α-fetoprotein (AFP) and albumin were studied in Sprague-Dawley rats and man by immunocytochemical localization of each protein in the liver and by its quantitation in serum at differen periods of normal intrauterine and extrauterine life. The proteins were present only in the cytoplasm of hepatocytes. During physiologic development, an inverse relationship existed between the serum concentrations of the two proteins; the serum concentration for each appeared to be directly related to the number of hepatocytes synthesizing it. AFP-containing cells were randomly distributed, while albumin-containing cells were more uniformly arranged. Both, however, were often preferentially located around venous channels. The last AFP-containing cells to disappear with advancing postnatal age were around the hepatic veins. When both proteins were present in serum, several hepatocytes appeared to synthesize the two simultaneously, although other hepatocytes contained only one protein. It is unlikely that in the physiologic state different populations of hepatocytes are assigned to synthesize AFP and albumin separately.

1968 METABOLISM OF STEROID AND AMINO ACID MOIETIES OF CONJUGATED BILE ACIDS IN MAN. V. EQUATIONS FOR THE PERTURBED ENTEROHEPATIC CIRCULATION AND THEIR APPLICATION. (Eng.) Hoffman, N. E.; Hofmann, A. F. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Gastroenterology* 72(1):141-148; 1977.

Equations previously developed to describe the enterohepatic circulation of the major biliary bile acids in man were modified to predict the effect of prototypic perturbations of the enterohepatic circulation on biliary bile acid composition and the pattern of amino acid conjugation. For the steroid moiety, the effects of bile acid feeding, increased recycling frequency, decreased intestinal conservation, and increased dehydroxylation were simulated. These simulations indicated that the size of the exchangeable bile acid pool for any circulating bile acid (steroid moiety) is related to the balance between input (from hepatic or bacterial formation) and intestinal loss. For the amino acid moiety (glycine or taurine), the effect of increased deconjugation or preferential loss of one of the amino acid moieties was simulated. These simulations indicated that the amino acid composition of biliary bile acids does not necessarily reflect the proportion of amino acids used for conjugation (input), but rather the balance between input and loss. Because the above variables may vary widely and independently, analysis of biliary bile acid composition in terms of the steroid moiety or the glycine-taurine ratio *per se* cannot be used to infer the relative rates of input or conjugation.

1969 METABOLISM OF CHENODEOXYCHOLIC ACID IN HAMSTERS. (Eng.) Tateyama, T.; Katayama, K. (Dept. Drug Metabolism, Eisai Co., Ltd., Koishikawa, Bunkyo-ku, Tokyo 112, Japan). *Lipids* 11(12):845-847; 1976.

The metabolites of chenodeoxycholic acid (CDCA) were determined in the bile and feces of male Golden hamsters after the p.o. administration of [^{14}C]CDCA (1 mg/kg). The radioactive bile acids were analyzed by thin layer chromatography and identified by the isotope dilution method. Twenty-four hours after radioactive CDCA administration, most of the radioactivity obtained from the gallbladders of bile fistula animals was unchanged CDCA (75.9-85.2%); the most predominant CDCA metabolite in the bile was 7-ketolithocholic acid (8.0-10.0%), followed by an unknown fraction 2 (1.1-5.2%), and lithocholic acid (0.5-0.9%). In the feces obtained 1 week after CDCA administration, lithocholic acid was the most predominant CDCA metabolite (53.1-68.2%), and unchanged CDCA comprised only 3.3-7.1% of the total radioactivity. Dehydrolithocholic acid and isolithocholic acid comprised 2.1-3.7% and 5.2-8.9% of the total radioactivity, resp. After the multiple dosing of [^{14}C]CDCD for 6 days, β-muricholic acid was identified in both the bile and the feces.

1970 EFFECT OF SULFATE AND NON-SULFATED GASTRIN AND OCTAPEPTIDE-CHOLECYSTOKININ ON CAT GALL BLADDER IN VITRO. (Eng.) Chowdhury, J. R.; Berkowitz, J. M.; Praissman, M.; Fara, J. W. (Albert Einstein Coll. Medicine, Bronx, NY). *Experientia* 32(9):1173-1175; 1976.

The isomeric tension responses to sulfated (G-17-S) and nonsulfated (G-17-NS) porcine gastrin and sulfated (OP-S) and nonsulfated (OP-NS) synthetic C-terminal octapeptide of cholecystokinin (CCK) were compared in strips of cat gallbladder. The maximal response to each hormone and the dose required to produce half the maximal response (D_{50}) were obtained both by direct observation and by linear transformation of Michaelis-Menten constants. There was no significant difference between the maximal isomeric tension responses obtained with OP-S and OP-NS. There were no significant differences in maximal responses obtained with G-17-S, G-17-NS, and nonsulfated synthetic human gastrin I (HSG-NS); the maximal response obtained with each of the three gastrins averaged 70% of that obtained with OP-S. When the respective D_{50}'s were compared, OP-S was nearly 1,000 times more potent than OP-NS, while G-17-S was about 10 times more potent than G-17-NS and HSG-NS. The large difference in potency observed between OP-S and OP-NS is consistent with effects reported in *in vitro* guinea pig gallbladder and on rat pancreatic secretion, and emphasizes the importance of sulfation of the seventh position tyrosine.

1971 ENZYME HISTOCHEMICAL STUDY ON FAT-STORING CELLS (SO-CALLED ITO'S CELL) OF LIVER.

(Eng.) Tanaka, M.; Kosakai, M.; Inomata, I.; Takaki, K.; Ishikawa, E. (Jikei Univ. Sch. Medicine, Japan). *Acta pathol. Jpn.* 26(5):581-588; 1976.

Fat-storing cells of normal and abnormal human liver were histochemically studied. Fat-storing cells in fresh frozen sections of normal human liver, which were fixed for 2 min in 70% cold ethanol, incubated, and then fixed in 1% osmium tetroxide, showed no alkaline phosphatase, acid phosphatase, or esterase activity. They did demonstrate a marked γ-glutamyl transpeptidase activity similar to that observed in fibroblast-like cells or in fibers of fibrotic areas of the liver, suggesting the possibility of the enzyme's participation in fiber protein synthesis. This possibility is further strengthened by the fact that fibroblast-like cells, which are morphologically similar to fat-storing cells, are found in the fibrotic area of liver parenchyma. Whereas under normal conditions, fat-storing cells participate in the formation of fibers supporting the sinusoidal wall, under abnormal conditions (chronic hepatitis), they gradually change their shape with the loss of fat droplets and are transformed into fibroblast-like cells.

1972 EFFECTS OF ACETOXYCYCLOHEXIMIDE ON THE METABOLISM OF HEPATIC TRIGLYCERIDES IN THE RAT.

(Eng.) Sabesin, S. M. (Univ. Tennessee Coll. Medicine, Memphis, TN 38163). *Exp. Mol. Pathol.* 25(2):227-235; 1976.

The effect of acetoxycycloheximide (ACH) on hepatic triglyceride metabolism in albino Sprague-Dawley rats was investigated. In rats fasted overnight who were given an i.p. injection of ACH (0.25 mg/kg) at 0 hr followed by a second dose at 3 hr, the hepatic triglycerides (HTG) ranged from 4.9 ± 1.3 mg/g at 1.5 hr after ACH to 8.2 ± 1.4 mg/g at 24 hr after ACH, compared to a control value of 4.5 ± 1.6 mg/g. Plasma triglycerides (PTG) in these rats ranged from 15.0 ± 4.4 mg/dl at 1.5 hr to 28.9 ± 9.0 mg/dl at 5 hr after ACH, compared with 24.8 ± 12.0 mg/dl for controls. Rats given ACH (0.5 mg/kg, i.p.) at 0 hr after overnight fasting and a second dose at 3 hr showed HTG values which ranged from 3.0 ± 0.8 mg/g at 6 hr to 8.1 ± 1.1 mg/g at 24 hr after ACH, compared with a control value of 3.8 ± 1.4 mg/g; PTG values ranged from 24.7 ± 6.4 mg/dl at 6 hr to 56.1 ± 11.5 mg/dl at 24 hr after ACH, compared with 22.6 ± 10.6 mg/dl for controls. Levels of plasma free fatty acids (FFA) were compared with HTG and PTG at various times in rats given ACH (0.25 mg/kg, i.p.) after 14 hr of fasting and then a second injection 3 hr later. The FFA levels ranged from 0.463 ± 0.122 μM/ml at 2 hr to 0.510 ± 0.112 μM/ml at 4 hr after ACH, compared with a control value of 0.508 ± 0.125 μM/ml. PTG
ranged from 23.9 ± 12.0 mg/dl at 2 hr to 42.7 ± 26.4
mg/dl at 4 hr after ACH (control: 25.8 ± 8.5 mg/dl)
and HTG ranged from 3.4 ± 2.1 mg/g at 6 hr to 4.4 ±
0.93 mg/g at 2 hr after ACH (control: 3.6 ± 1.2 mg/g
Overall, ACH did not cause significant increases in
plasma FFA or in HTG or a significant decrease in
PTG. These results demonstrate that hepatic protei
synthesis inhibition alone is not sufficient to
produce liver triglyceride accumulation, and emphas
the importance of FFA mobilization in the pathogenesis of fatty liver.

1973 PRELIMINARY REPORT. PROLONGED BILIARY FI
TULIZATION IN THE RAT WITHOUT INTERRUPTIO
OF THE ENTEROHEPATIC CYCLE.

(Eng.) Lipsky, M. H.; Berkley, S. (Rhose Island Hosp., Providence, RI 02902). *J. Surg. Res.* 22(1):65-68; 1977.

A technique that permits the collection of bile secretions from laboratory animals intermittently ove
a prolonged period of time without interrupting the
enterohepatic cycle and without permanently immobil
izing the animals is described. Charles River C.O.
male rats were used. Indwelling catheters are plac
in the proximal and distal ends of the bile duct i
a closed-loop shunt system. The free ends of the
two catheters are brought out from the abdomen and
tunneled to the posterior aspect of the neck via a
s.c. route. The free ends are then connected with
Teflon connector, and the base of the connector is
implanted s.c. Bile collections can be obtained b
restraining the animal in a cage and removing the
cap of the connector. Using this procedure, no re
flux of gastrointestinal juices or dilatation of t
bile duct was observed. This technique permits co
tinuous sampling of uncontaminated bile without in
troducing any apparent modifications that could al
the homeostatic mechanisms of bile secretion.

1974 TRANSPLANTATION OF LIVER CELLS IN AN AN
MODEL OF CONGENITAL ENZYME DEFICIENCY D
EASE: THE GUNN RAT.

(Eng.) Sutherland, D. E. R.
Matas, A. J.; Steffes, M. W.; Simmons, R. L.; Naj
ian, J. S. (Univ. Minnesota Health Sciences Cente
Minneapolis, MN 55455). *Transplant. Proc.* 9(1):
319; 1977.

To assess the feasibility of transplanting liver
to supply a missing enzyme in the treatment of co

enital enzymatic deficiency diseases, hepatocytes rom heterozygous Gunn rats were transplanted to omozygous recessive uridine diphosphate glucuronyl ransferase (UDPGT)-deficient Gunn rats, and the efect on bilirubin metabolism was determined. Cells btained from the equivalent of 2 g of adult liver ere infused into the portal vein of 16 homozygous ats and dispersed i.p. in 8 homozygous rats. Five ats received spleen cells from heterozygous adults ia the portal vein, and four additional rats received eonatal donor liver cells. A significant and lastng reduction in plasma bilirubin concentration in he hyperbilirubinemic homozygous Gunn rats was seen nly in the group that received hepatocytes into the ortal vein. At 12 weeks, the mean bilirubin level n this group was 6.7 ± 0.3 mg/100 ml ($p<0.01$), and or the group receiving neonatal hepatocytes, it was .5 ± 1.4 mg/100 ml ($p<0.05$). However, the bilirubin evel never fell to normal (<0.5 mg/100 ml in heteroygous Gunn rats). The results show that transplanation of allogenic hepatocytes to the portal vein an lower plasma bilirubin in congenitally jaundiced unn rats. The potential application for clinical ransplantation requires further study.

975 LIVER REGENERATION: CULTURAL CHARACTERISTICS OF REMNANT LIVER CELLS FOLLOWING A ECOND PARTIAL HEPATECTOMY. (Eng.) Sera, Y.; Sakaoto, Y.; Koga, Y.; Hays, D. M. (Univ. Southern Caliornia Sch. Medicine, 4650 Sunset Blvd., Los Angeles, A 90027). *Experientia* 33(2):194-195; 1977.

38% hepatectomy in mature male Wistar rats was ollowed in 24-72 hr by a 30% hepatic resection to tudy the influence of a prior hepatic resection on he *in vitro* growth capacity of remnant liver cells emoved less than 46 hr after the second resection. ixty rats were subjected to a medial lobectomy (38% esection), followed 24, 40, and 72 hr later by a econd (left) lobectomy. At intervals of 8, 24, 36, nd 48 hr following the second resection, the animals ere sacrificed, and the liver tissue was cultured. ontrols had single 68% or 30% resections. There was o *in vitro* cell survival in tissue removed 8, 24, and 6 hr following single hepatic resection in controls, ut tissue removed 48 hr following single resection howed maximum growth (546 ± 24 cells/plate x 10^3 fter 68% resection; 168 ± 32 cells/plate x 10^3 after 0% resection). Tissue removed at all intervals folowing a second resection survived. Following the 0 hr and 72 hr (second) resections, cell survival as increased with each lengthening of interval post esection, i.e., 8 hr post resection to 48 hr post esection. A second hepatic resection is not followed y a period of growth inhibition, a phenomenon that s always seen up to 46 hr following a single resecion. This suggests that the growth inhibition after single hepatectomy is not related to the trauma of he liver excision.

976 PREVENTION OF GALLSTONE FORMATION IN RABBITS BY THE ORAL ADMINISTRATION OF KANAMYCIN. Eng.) Carlisle, V. F.; Tasman-Jones, C. (Univ. Auckand Sch. Medicine, Auckland, New Zealand). *Surg. ynecol. Obstet.* 144(2):195-198; 1977.

The ability of kanamycin to prevent gallstones and the effect of the antibiotic on bile composition were studied in rabbits. Animals fed a diet containing 40% casein, 15 oleic acid, and 45% laboratory pellets developed glycoallodeoxycholic acid and glycodeoxycholic acid gallstones. The p.o. administration of kanamycin prevented allo bile acid stone formation in the oleic acid-fed rabbit, without leading to cholesterol gallstone formation. Kanamycin reduced the concentration of allodeoxycholic acid in the bile of oleic acid-fed rabbits from 16.6 ± 4.1% of total bile acids to 1.1 ± 1.1% with a reciprocal increase in deoxycholic acid concentration. The allodeoxycholate concentration was far below that found in control bile samples (10.2 ± 2.3%). If the effect of kanamycin on the bile composition is by its antibiotic action, the importance of a hepatic contribution to allodeoxycholate stone formation is eliminated.

1977 LINCOMYCIN-INDUCED CHOLECYSTITIS AND GALLSTONES IN GUINEA PIGS. (Eng.) Scott, A. J. (Univ. Auckland Sch. Medicine, Auckland, New Zealand). *Gastroenterology* 71(5):814-820; 1976.

The effect of lincomycin on the guinea pig gallbladder was investigated to examine the genesis of the drug-induced lesions and the nature of lincomycin toxicity. Guinea pigs given lincomycin (60 mg/kg/day, s.c.) showed a striking increase in the renewal of epithelial cells in the gallbladder. This was detectable after only 24 hr of treatment. By 48 hr, a precipitate consisting predominantly of calcium and bilirubin had formed in the gallbladder. Gallbladder bile glycoprotein concentrations rose progressively. At 8 days, epithelial dysplasia was marked. Treatment was discontinued at 9 days. In guinea pigs that survived beyond 34 days, new tubuloalveolar glands had formed focally in the body and fundus of the gallbladder. Multiple calcium-containing stones were present. The failure to culture bacteria from bile, the failure of the bile salt pattern to change, and the progressive nature of the epithelial injury suggested that the changes resulted from a direct toxic effect and were not dependent on the antibiotic activity of this drug. It is concluded that damage to the epithelium of the gallbladder preceded the formation of a precipitate and initiated histological changes that culminated, at the time that the precipitate became organized into stones, in glandular metaplasia.

1978 UNILATERAL HEPATIC DUCT OBSTRUCTION IN THE PRIMATE. (Eng.) Strasberg, S. M.; Petrunka, C. N.; Ilson, R. G. (Medical Sciences Bldg., Univ. Toronto, Toronto, Ontario M5S 1A8 Canada). *Surgery* 81(1):91-99; 1977.

The effects of obstruction of one hepatic duct were investigated in two studies in the rhesus monkey. A model to divide bile flow from the two sides of the liver was developed in the first study. Bile flow from one side of the liver was obstructed, and backflow from the obstructed biliary tract was investigated in five animals. Test solutions containing BSP and conjugated $[^{14}C]$cholic acid were introduced into the obstructed side of the liver at pressures below and above the maximum secretory pressure. These solutes were detected in the circulation and in the bile on the free side of the liver. BSP, secreted on the free side, was conjugated normally (52.7%) for this species. There was also backflow of water from the obstructed side and continuing secretion into the obstructed side. There were no functionally significant biliary communications between the two separately cannulated portions of the liver. In the second study, graded unilateral obstruction and recovery were studied in five animals. Bile flow, [^{14}C]erythritol clearance, and bile acid, bilirubin, and bicarbonate secretion rates were reduced during obstruction and recovery. The bile:plasma ratio of [^{14}C]erythritol fell significantly (1.13 to 0.97, $p<0.05$) and the bicarbonate concentration increased during partial obstruction ($p<0.05$). On the free side, bile flow, [^{14}C]erythritol clearance, and bile acid secretion rates increased during obstruction. The increase in bile flow was due largely to an increase in canalicular bile acid-dependent flow. The studies indicate that reduced bile flow during acute obstruction is due to both hydrostatic backflow and secretory failure. The latter occurs mainly at the canalicular level, whereas the bile ductules are spared. During acute obstructions, compensations in unobstructed portions of the liver are due to increased secretion of solute at the canaliculus.

1979 APOLLO GASTROINTESTINAL ANALYSIS. (Eng.) Nichols, B. L.; Huang, C. T. L. (Baylor Univ., Houston, TX). 20 pp; 1975 [available through National Technical Information Services, Washington DC, Document No. N75-32734/6WJ].

SECRETION AND METABOLISM

Intestine

2058 MECHANISM OF PRODUCTION OF INTESTINAL SECRETION BY ELEVATED VENOUS PRESSURE. (Eng.) Yablonski, M. E.; Lifson, N. (Univ. Minnesota Medical Sch., Minneapolis, MN 55455). *J. Clin. Invest.* 57(4):904-915; 1976.

The nature of increased fluid secretion by the smal intestine in response to elevated venous pressure was investigated in intestinal loops in dogs and i preparations using the Wells clamp. No net secretion occurred at venous pressure below 35 cm H_2O, t at venous pressures above that threshold, the ount of secretion was essentially linearly related the increment in venous pressure. The rate of crease was approximately 0.045 ml/min/100 g/cm 0. Only small rates of lymph flow were observed low 30 cm H_2O, but increases above that threshold sulted in increased lymph flow roughly propor- onal to increments in venous pressure. Capillary ltration similarly increased linearly with incre- nts of venous pressure above 30 cm H_2O. The lymph ulin concentration was approximately equal to that plasma at all venous pressures. The secretion plasma concentration (S:P) ratios for inulin and abinose were as high as 3 and 1.5, resp., at low tes of secretion, but this ratio decreased as secre- on rates were increased. Protein concentration in e secretion also varied with the rate of secre- on, with S:P ratios of 0.17-0.55 at low rates and duction to 0.17 at higher rates of secretion. The otein concentration of the lymph varied with ven- s pressure, being close to 67% of the plasma level normal venous pressures and falling to 25-50% of asma concentration at higher venous pressures. stribution of protein in the secretion was more ke that of lymph than plasma. Osmolality and dium concentration of the secretion were not sig- ficantly different from that of plasma, but po- ssium and chloride concentrations in the secretion re higher than the plasma concentration. Mucosal ter content did not increase until venous pres- res reached 30 cm H_2O, but nonmucosal water con- nt increased with increasing venous pressure. In- stinal secretion produced by elevated venous pres- re is probably secretory filtration, a passive ocess; the driving force for secretion is an in- ease in mucosal tissue fluid pressures to values 4-6 cm H_2O. The transepithelial channels are obably intercellular, since they are large enough permit passage of inulin and plasma proteins. e threshold value for secretion and associated anges may be explained by dilution of the tissue uid protein colloid osmotic pressure in a small bepithelial, juxtacapillary compartment.

)59 EFFECT OF INDOMETHACIN ON CHOLERA-INDUCED FLUID MOVEMENT, UNIDIRECTIONAL SODIUM
LUXES, AND INTESTINAL cAMP. (Eng.) Wald, A.; Gotter- r, G. S.; Rajendra, G. R.; Turjman, N. A.; Hendrix, . R. (Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 1205). *Gastroenterology* 72(1):106-110; 1977.

e effects of indomethacin on net fluid movement and idirectional Na fluxes were measured in rabbit je- nal loops exposed to cholera enterotoxin (CT), and ese findings were correlated with intestinal cAMP vels. In untreated animals (no indomethacin), CT ops secreted 0.37 ml/cm/4 hr, compared to absorp- on in control loops of 0.23 ml/cm/4 hr ($p<0.001$). indomethacin (10 mg/kg, i.v. and 10 mg/kg, s.c.)- eated animals, there was a striking reduction of cretion in CT loops (0.07 ml/cm/4 hr, $p<0.001$). sorption in control loops in indomethacin-treated imals was greater than in that untreated animals .42 ml/cm/4 hr, $p<0.02$). Unidirectional Na luxes were greatly depressed in indomethacin-treated imals at 1 hr; in both CT and control loops. is effect disappeared by 4 hr. Intestinal cAMP levels in CT loops, although not elevated at 1 hr despite the onset of secretion, were significantly elevated at 4 hr. Indomethacin did not alter cAMP levels at 1 and 4 hr in either cholera or control loops. These studies support the view that prostaglandin synthesis is not involved in CT-induced elevation of intestinal cAMP. Indomethacin may depress intestinal secretion by inhibiting a prostaglandin-mediated step beyond the generation of cAMP or by acting on some other, as yet unidentified, biological mechanism involved in intestinal secretion.

2060 EFFECT OF PROPRANOLOL ON BILE ACID- AND CHOLERA ENTEROTOXIN-STIMULATED cAMP AND SECRETION IN RABBIT INTESTINE. (Eng.) Taub, M.; Bonorris, G.; Chung, A.; Coyne, M. J.; Schoenfield, L. J. (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048). *Gastroenterology* 72(1):101-105; 1977.

The organ specificity of deoxycholic acid (DCA) and cholera enterotoxin (CE), and the selectivity of propranolol (Pr) inhibition were assessed. Three colonic and three jejunal loops were prepared in each of 8 rabbits treated i.v. with Pr (4 mg/kg) 30 min before loop construction and in each of 10 untreated control rabbits. DCA (6 mM; 1 ml), CE, heat-inactivated CE (10 μ/ml), or 0.9% NaCl were injected as basal controls in random order into each of the loops. The volume of luminal fluid and mucosal adenylate cyclase (AC) were measured in each intestinal loop 5 hr later. DCA in the colon stimulated AC 2-fold ($p<0.01$) and luminal fluid 15-fold ($p<0.01$). CE in the jejunum stimulated AC 2.3-fold ($p<0.01$) and luminal fluid, 9-fold ($p<0.01$). No significant effects on volume or AC occurred in response to CE in the colon or to DCA in the jejunum. Pr pretreatment completely prevented the stimulation of AC and luminal fluid by DCA in the colon, but did not affect the action of CE in the jejunum of the same animals. The results show that DCA and CE are organ-specific stimulants of cyclic AMP systems and that Pr is a selective inhibitor of certain inducers of cyclic AMP and net secretion.

2061 STIMULATION OF COLONIC GLYCOPROTEIN SYNTHESIS BY DIBUTYRYL CYCLIC AMP AND THEOPHYLLINE. (Eng.) LaMont, J. T.; Ventola, A. (Peter Bent Brigham Hosp., Boston, MA 02115). *Gastroenterology* 72(1):82-86; 1977.

Because bile salts, cholera toxin, and *Escherichia coli* enterotoxin have been found to stimulate the release of intestinal goblet cell mucus, the effects of dibutyryl cyclic AMP (B_2cAMP) and theophylline on glycoprotein synthesis in rabbit colon were studied in mucosal organ cultures using ^{3}H-glucosamine as a precursor. Addition of B_2cAMP (1 mM) to culture medium caused a significant increase in glycoprotein synthesis after 12 and 24 hr, compared with biopsies cultured in control medium. The increase in glycoprotein synthesis was observed only if the cyclic nucleotide was present continuously in the incubation medium for at least 12 hr. The stimulatory effect of B_2cAMP on ^{3}H-glucosamine incorporation was blocked by

1 mg/ml cycloheximide. B_2cAMP also stimulated mucosal uptake of glucosamine into the intracellular pool and markedly enhanced the specific activity of mucosal galactosyltransferase. The addition of 5 mM theophylline caused a greater than twofold increase in cAMP levels, which was also accompanied by an increase in glucosamine uptake and incorporation into mucosal glycoproteins. The results demonstrate that elevation of intracellular cAMP concentration in colon epithelium *in vitro* is associated with an increase in glycoprotein synthesis. These effects may be mediated in part by an increased uptake of glycoprotein precursors such as glucosamine, and an increased activity of glycoprotein synthetic enzymes.

2062 SOLUBILIZATION, PARTIAL PURIFICATION AND RADIOASSAY FOR THE INTRINSIC FACTOR RECEPTOR FROM THE ILEAL MUCOSA. (Eng.) Cotter, R.; Rothenberg, S. P. (New York Medical Coll., 1249 Fifth Ave., New York, NY 10029). *Br. J. Haematol.* 34(3):477-487; 1976.

The purification of a macromolecule that binds intrinsic factor saturated with vitamin B_{12} solubilized from guinea pig ileum was monitored by a radiometric assay. The intrinsic factor-[^{57}Co]vitamin B_{12} complex coupled to the solubilized receptor precipitated at 15% sodium sulphate, while intrinsic factor-[^{57}Co]B_{12} alone remained soluble at this salt concentration. This radioassay also permitted the *in vitro* study of the interaction of the solubilized receptor and intrinsic factor saturated with ^{57}CoB_{12}. The receptor did not bind intrinsic factor-[^{57}Co]B_{12} below pH 5, while binding was observed to pH 9.0. Binding was equivalent at 37 C and 25 C, but was markedly reduced at 4 C and 56 C, and was destroyed at 100 C. The receptor resisted 60 min of digestion by trypsin, chymotrypsin, pronase, and subtilisin. After 180 min of digestion, pronase and subtilisin inactivated 90% and 41% of the receptor, resp., whereas trypsin and chymotrypsin inactivated only 21% and 23%, resp. Trisodium EDTA inhibited the binding of intrinsic factor-[^{57}Co]B_{12} to the receptor, and this inhibition was reversed by the addition of excess Ca^{2+}. Kinetic analysis of the reaction indicated a maximum velocity of 0.083 nmol intrinsic factor bound B_{12}/min with a K_m of 1.36×10^{-10} M. The solubilized receptor had a greater affinity for intrinsic factor bound to vitamin B_{12} than for intrinsic factor free of vitamin B_{12}. The solubilization of this intrinsic factor receptor without chemicals suggests that it is not an integral component of the microvillus membranes hydrophobically bonded to the lipid matrix, but rather a peripheral protein weakly associated with the membrane by noncovalent interaction.

GENERAL

2096 UNSTIRRED LAYER THICKNESS IN PERFUSED RAT JEJUNUM IN VIVO. (Eng.) Winne, D. (Pharmakologisches Institut, Universitat Tubingen, Wilhelmstrasse 56, D-7400 Tubingen, W. Germany). *Experientia* 32(10):1278-1279; 1976.

A better mixing of the luminal solution and a reduction of the unstirred layer in the rat jejunum was achieved *in vivo* by altering a previously reported *in vitro* method, and the effective unstirred layer thickness was calculated. The method involves the simultaneous perfusion of a buffered solution and air, so that alternate segments of fluid and air pass the lumen ("segmented flow"). Jejunal loops of male rats were perfused with a buffered solution containing ^{14}C-labeled L-phenylalanine and phenol red as volume marker. The appearance rate of L-phenylalanine in intestinal venous blood collected from the descending jejunal vein was calculated from the weight (g) and the ^{14}C-activity (μCi/ml) of the blood using its specific weight (g/ml), the specific activity (μCi/mol), the duration of the sampling period (min), and the wet tissue weight of the loop (g). In three consecutive 15-min experimental periods, the L-phenylalanine-containing solution was perfused in the following manner: 0.5 ml/min (treatment A), 0.5 ml/min + 0.5 ml/min air (treatment B), and 1 ml/min (treatment C). The absorption rate after treatment B was significantly increased ($p<0.001$) over that after treatment A, the absorption rate being higher by a factor of 1.74, and after treatment C, the absorption rate being higher by a factor of 1.52. The unstirred layer thickness, calculated by determining the change of the absorption rate using segmented and nonsegmented flow, was about 0.5 mm, which exceeds the thickness reported *in vitro* (150-200 μm). Higher K_m values previously obtained *in vivo* for carrier-mediated transport processes in the intestine may be explained, at least in part, by the larger effective thickness of the unstirred layer.

2097 RADIOIMMUNOASSAY MEASUREMENT OF SECRETIN HALF-LIFE IN MAN. (Eng.) Kolts, B. E.; McGuigan, J. E. (Hillis Miller Health Center, Univ. Florida, Gainesville, FL 32601). *Gastroenterology* 72(1):55-60; 1977.

Using a secretin radioimmunoassay, fasting serum concentrations were determined in dogs and humans; the serum secretin half-life in man and responses to duodenal acidification and to a protein meal in dogs were also measured. High titer antibodies to secretin were produced in rabbits by immunization with pur fied porcine secretin conjugated to bovine serum albumin in complete Freund's adjuvant. Synthetic porcine secretin was labled with ^{125}I using chloramine-T, and radiosecretin was purified using talc-silica and fibrocellulose powder. Specificity of antibodies to secretin was extensively evaluated in studies examining cross-reactivity with other naturally occurring hormones, parallelism of serum dilutions and secretin standards, quantitative recovery of secretin added to serum samples, and changes in circulating immunoreactive secretin in response to intraduodenal acidification. The mean fasting serum secretin concentration in 10 dogs was 65 ± 5 pg/ml, and in 21 healthy human volunteers, it was 69 ± 5 pg/ml. In response to intraduodenal instillation of 10 mEq of HCl, portal venous secretin concentrations increased from a mean fasting value of 52 to 450 pg/ml within 2 min; peripheral venous secretin increased from 66 to 229 pg/ml within 5 min. No significant changes in peripheral serum immunoreactive secretin concentrations were identified in dogs after a protein meal. Secretin administered i.v. in man disappeared from the ci culation with a mean half-life of 4.06 ± 0.82 min.

2098 ROLE OF MECHANICAL STIMULATION IN MAINTAINING SMALL INTESTINAL MASS IN THIRY-VELLA LOOPS IN THE RAT. (Eng.) Fenyo, G. (Karolinska sjukhuset, S-104 01 Stockholm 60, Sweden). *Eur. Surg. Res.* 8(5):419-427; 1976.

The effect of mechanical stimulation on small intestinal mass was evaluated by constructing two 10-cm-long Thiry-Vella (TV) loops in each of 20 Sprague-Dawley rats. An elastic-plastic device, which served as a source of continuous intraluminal mechanical stimulation, was fixed in one of the loop Two weeks later, the jejunum, ileum, and both TV loops were biopsied. Wet and dry weight per 3 cm intestine, villus height and muscular thickness, were determined. Both TV loops were atrophic. The

t and dry weights in the mechanically stimulated
op (165 ± 7 and 35 ± 1.4 mg/3 cm intestine, resp.)
re significantly greater than in the nonstimulated
op (115 ± 6 and 24 ± 1.3 mg/ 3 cm, resp., $p<0.001$).
scular thickness in the stimulated loop (113 ± 7
) was also significantly greater than that in the
stimulated loop (76 ± 6 μm, $p<0.001$). The villus
ight was not significantly affected by the mechan-
al stimulation. The experiments demonstrate that
e effect of mechanical stimulation on the food-
prived small intestine is limited to a certain
gree of muscular hypertrophy, resulting in a les-
r degree of atrophy expressed in terms of wet and
y weight of the intestine.

99 COLONIC EPITHELIAL CELL PROLIFERATION AFTER 40 PERCENT SMALL INTESTINAL RESEC-

ON: AUTORADIOGRAPHIC STUDIES IN THE RAT. (Eng.)
Dermott, F. T.; Roudnew, B. (Alfred Hosp., Prahran
81, Victoria, Australia). *Virchows Arch [Cell*
thol.] 22(4):353-357; 1976.

e kinetics of the colonic crypt cell population
re investigated by autoradiography with tritiated
ymidine in male Sprague-Dawley rats 60 days after
e resection of a jejunal segment equivalent to
% of the length of the small intestine. No sig-
ficant differences ($p>0.1$) were found in the mean
tal number of cells per crypt cell column, the
an number of labeled cells per crypt cell column,
beling and mitotic indices, or the columnar globlet
ll indices in the colons of sham-operated and ex-
rimental rats. Labeled cells were distributed with
milar frequency over identical cell positions in
th groups, and the sizes of the proliferative and
ture cell zones were comparable. The absence of
ange in the colon after 40% intestinal resection
es not support the proposed existence of a systemic
ctor regulating both small intestinal and colonic
ithelial cell population kinetics after small
testinal resection.

00 THE EFFECT OF ISCHEMIC VILLUS CELL DAMAGE ON CRYPT CELL PROLIFERATION IN THE SMALL

TESTINE: EVIDENCE FOR A FEEDBACK CONTROL MECHA-
SM. (Eng.) Rijke, R. P. C.; Hanson, W. R.; Plais-
r, H. M.; Osborne, J. W. (Dept. Cell Biology and
netics, Erasmus Univ. Rotterdam, P.O. Box 1738,
tterdam, Netherlands). *Gastroenterology* 71(5):
6-792; 1976.

test the hypothesis that the number of villus
lls regulates crypt cell proliferation in the
all intestinal epithelium, the villus cell popu-
tion in male Glaxo-Wistar rats was reduced by
amping the superior mesenteric artery and vein
r 1 hr, and the effects on the intestinal epi-
elium were studied during the first 24 hr. Tem-
rary interruption of the blood flow to the small
testine led to a 50% decrease in the number of
nctional villus cells within 2 hr; preferentially,
lls from the upper part of the villus were lost,
d the number of crypt cells was not affected.
is reduction in the number of villus cells led to
increase in the percentage of labeled crypt cells
ter pulse labeling with [^{3}H]thymidine and an expansion of the proliferative cell compartment in the crypt. After a peak of proliferative activity at 16 hr, the investigated crypt cell kinetic parameters approached control values after 24 hr, as did the number of villus cells. The enzyme activities of nonspecific esterase and neutral α-glucosidase showed marked decreases in isolated crypt and villus cell compartments as crypt cell proliferation increased. These data support the hypothesis of a feedback control of crypt cell proliferation by the functional villus cells and confirm earlier data on the influence of changing cell kinetics on crypt cell maturation. Additional data obtained after creating temporary ischemia in part of the small intestine support the view that the feedback control of proliferation by the villus cells is a local control mechanism.

2101 INTESTINAL RECIRCULATION IN THE MANAGEMENT OF EXPERIMENTAL SHORT BOWEL SYNDROME.

(Spa.) Lopez Perez, G. A.; Gaztambide Casellas, J.; Quadri Duque, A. (San Juan de Letran, 9, 5 C, Malaga, Spain). *An. Esp. Pediatr.* 8(3):243-248; 1975.

Following major resection of 80% of the intestine of 33 newborn dogs, the animals underwent end-to-end anastomosis (14), isoperistaltic ileal loop operation (16), or Mackby circular loop operation (3). Seven animals died within 24-36 hr of the first resection; two animals died from accidents and six died of peritonitis. Of the 18 surviving animals, 7 of 8 with end-to-end anastomosis died of malabsorption; malabsorption and peritonitis resulted in death in 3 and 2, resp., of the 9 dogs with isoperistaltic ileal loops. The authors favor the isoperistaltic ileal loop procedure of intestinal resection as it avoids intraluminal stasis and secondary abnormal bacterial proliferation.

2102 EXPERIMENTAL MODEL OF ULCERATIVE COLITIS.

(Eng.) Ceredig, R.; Henderson, D. C.; Nairn, R. C. (Monash Univ. Medical Sch., Prahran, Melbourne, Australia). *Nature* 266(5597):74-75; 1977.

The induction of inflammatory ulcerative changes in rat colon mucosa, as an experimental model of ulcerative colitis, is reported. Rat fetal colon implants beneath the renal capsule of syngeneic adult Sprague-Dawley rats developed, by 6 days, acute inflammation; by 12 days, ulceration of the mucosa morphologically indistinguishable from active ulcerative colitis was present. Plasma cells were present, and the ulcerated mucosa was infiltrated by neutrophil granulocytes. Over the succeeding days, the mucosa became depleted of mucin-secreting cells, and by 20 days, it was largely destroyed. With a single exception, the implanted syngeneic fetal colon remained structurally and functionally viable after 28 days, as shown by vascularization by recipient blood vessels. The pathological changes were not attributable to sex-related antigenicity. Serum samples from most rats 10 days after implanting syngeneic fetal colon contained antibody reactive with fetal intestinal mucosa but not adult mucosa, as judged by indirect immunofluorescent staining; this indicates an immune reaction in adult rats to fetal antigens deficient in the adult animal. This rat system should provide a useful new model for investigating immunologically-determined colonic inflammatory disease.

2103 OXIDATION OF α-METHYLDOPA AND OTHER CATECHOLS BY CYTOCHROME P-450-GENERATED SUPEROXIDE ANION: POSSIBLE MECHANISM OF METHYLDOPA HEPATITIS.

(Eng.) Dybing, E.; Nelson, S. D.; Mitchell, J. R.; Sasame, H. A.; Gillette, J. R. (Dept. Environmental Toxicology, Natl. Inst. Public Health, Oslo 1, Norway). *Mol. Pharmacol.* 12(6): 911-920; 1976.

To determine whether the toxicity of α-methyldopa might be due to a reactive metabolite, $[^3H]$α-methyldopa was incubated with rat liver microsomes in the presence of an NADPH-generating system. A large amount of covalent binding occurred, but only in the presence of NADPH and oxygen (V_{max}=0.5 nmol/mg/min; K_m= 0.5 μM). The binding was inhibited by a $CO-O_2$ atmosphere (9:1), indicating the involvement of cytochrome P-450. However, α-methyldopa did not show P-450 binding spectra (type I, II, or III), and its covalent binding was inhibited by superoxide dismutase (15 μg/ml), ascorbic acid (1 mM), ethylenediamine (20 mM), and glutathione (1 mM), indicating that α-methyldopa was being oxidized by cytochrome P-450-generated superoxide anion to a reactive semiquinone and/or quinone. The covalent binding was inhibited by 42-79% by analogues such as L-dopa, dopamine, epinephrine, norepinephrine, and catechol, but not by 3-*O*-methyldopa, indicating a requirement for the unsubstituted catechol nucleus. Additional studies demonstrated that the rat microsomal system could be replaced by human hepatic microsomes or by a xanthine oxidase system, and the binding was again inhibited by superoxide dismutase. Metabolic activation by superoxide anion may play a role in the hepatotoxicity of this and other catechols, including hydroxylated estrogens.

2104 THE PATHOLOGY OF VIRAL HEPATITIS TYPES A AND B IN CHIMPANZEES: A COMPARISON.

(Eng.) Dienstag, J. L.; Popper, H.; Purcell, R. H. (Natl. Inst. Allergy and Infectious Diseases, Natl. Insts. Health, Bldg. 7, Room 310, Bethesda, MD 20014). *Am. J. Pathol.* 85(1):131-144; 1976.

The histologic manifestations in the livers of chimpanzees inoculated with hepatitis A and B virus were compared with each other, with those in man, and were correlated with biochemical, serologic, and virologic observations. The alterations in hepatitis A- and B-inoculated chimpanzee livers were similar to those seen in human hepatitis, but the lesions--particularly the hepatocellular necrosis--were far milder. The hepatocytic alterations in hepatitis A in chimpanzees were mainly restricted to the periportal areas, and the parenchymal changes were less severe than the portal inflammation. The lesions correlated well with biochemical changes, the presence of virus in the liver, and its shedding in the stool. Experimental type B hepatitis involved the entire lobular parenchyma, and was more severe in the lobular centers, while portal inflammation was less conspicuous. Biochemical alterations and presence of virus in the liver correlated with these lesions, and the antibody response was similar to that seen in man. The chimpanzee is a useful model for studying the pathogenesis of viral hepatitis; additional study of serial morphologic events may contribute to the understanding of the clinical differences between hepatitis types A and B.

2105 PARACETAMOL-INDUCED HEPATIC NECROSIS IN THE MOUSE--RELATIONSHIP BETWEEN COVALENT BINDING, HEPATIC GLUTATHIONE DEPLETION AND THE PROTECTIVE EFFECT OF α-MERCAPTOPROPIONYLGLYCINE.

(Eng.) Labadarios, D.; Davis, M.; Portmann, B.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, SE5 8RX, England). *Biochem. Pharmacol.* 26(1):31-35; 1977.

The mechanism by which α-mercaptopropionylglycine (α-MPG) reduces the hepatotoxicity of paracetamol in mice was investigated. The severity of hepatic necrosis in mice that received paracetamol 3.31 mmol/kg, p.o., was significantly greater than after a 2.65 mmol/kg dose, and the quantity of a reactive metabolite of the drug bound to hepatocyte macromolecules was significantly greater after the higher dose. α-MPG, given together with 3.31 mmol/kg paracetamol, afforded significant protection against hepatic necrosis, as assessed histologicall but had no significant effect on the quantity of paracetamol metabolite bound within the liver. α-MPG did not increase levels of reduced glutathion in the liver, nor did it prevent the fall in hepati glutathione content observed in animals receiving hepatotoxic doses of paracetamol without the protective agent. α-MPG had no effect on the metabolism of paracetamol, as judged by the urinary excretion of conjugates of the drug. It is conclud that binding of the reactive metabolite of paracetamol to hepatocyte macromolecules need not lead to hepatic necrosis, provided that sulfhydryl group are present in the liver to prevent the deleterious effects of such binding. This appears to be the mode of action for α-MPG.

2106 A CONTROLLED TRIAL OF GLUCAGON IN EXPERIMENTAL PANCREATITIS.

(Eng.) Waterworth, M. W.; Barbezat, G. O.; Hickman, R.; Terblanche, J. (Royal Infirmary, Birmingham, England). *Br. J. Sur* 63(8):617-620; 1976.

The value of glucagon infusion therapy was assessed in pigs with experimentally-induced pancreatitis. The condition was induced by the injection of bile (1.0 ml/kg) into the pancreatic duct immediately after the i.v. injection of secretin (1 U/kg). Macroscopic hemorrhagic pancreatitis ensued immediately, and was accompanied by a 5- to 10-fold increase in the serum amylase level. Eighteen hour after the induction of pancreatitis, 15 animals received a bolus of 0.5 mg glucagon, followed immediately by a continuous infusion of 15 μg/kg/hr for 6 hr, and 10 μg/kg/hr for a further 18 hr. Controls were given i.v. saline. Fourteen treated imals survived for 1 week, and three died within weeks, after which the remaining animals were crificed. Ten controls died within the first eek. Serum amylase levels in both groups began to ecline when infusion was commenced, but levels in e treated group were significantly lower than in e controls. Autopsy showed prominent peripan-reatic granulation tissue in the treated animals, significant incidence of pericarditis in both roups, and pancreatic pseudocysts in three controls d one treated animal. The results suggest that lucagon effectively reduces the mortality in pigs ith experimental pancreatitis and that a controlled linical trial of treatment is justified.

107 IS THE LESSER CURVATURE AN AREA ESPECIALLY SUSCEPTIBLE TO INJURY BY DUODENAL CONTENTS? Eng.) Lawson, H. H. (Baragwanath Hosp., Johannes-urg, South Africa). *Br. J. Surg.* 63(8):589-591; 976.

n dogs, the total duodenal contents were diverted n to the lesser curvature, and the subsequent hronic gastric mucosal reaction (CGMR) was examined n different areas of the stomach. Two dogs were acrificed 3 and 6 months, resp., after the duodenal ontents had been diverted; this was accomplished y transecting the duodenum in two places (near the tomach and 10 cm beyond the duodenojejunal flexure), ividing the descending branch of the left gastric rtery, anastomosing the proximal duodenal loop to he middle of the lesser curvature, and creating n end-to-end anastomosis between the cut end of he stomach and the distal loop. In both dogs, the toma was surrounded by an area of CGMR that spread utwards in all directions; after 3 months, the GMR had not reached the greater curvature, but fter 6 months, the whole greater curvature was ffected, except for a small area on the anterior nd posterior walls of the zone adjacent to the astric outlet. After 6 months, the reaction on he lesser curvature was limited mainly to the area f the stoma. The types of CGMR seen around the toma in both cases were pseudopyloric metaplasia nd intestinal metaplasia. In both experiments, he CGMR was most marked at the point of entry of he duodenal contents on the lesser curvature; his is either an indication that the lesser urvature is an area of increased susceptibility o injury or simply that this was the point of ntry of the duodenal contents, and hence the point f greatest stimulation. These results, and the indings of others, support the latter explanation. he reason that chronic gastric ulceration commonly ccurs along the lesser curvature may be that efluxing duodenal contents follow the anatomical osition of the lesser curvature.

108 INHIBITION OF STRESS ULCER FORMATION WITH SOMATOSTATIN IN RATS. (Eng.) Zierden, .; Hengst, K.; Wagner, H.; Gerlach, U. (Medizinische linik und Poliklinik, Universitat Munster, Westring , D-4400 Munster, W. Germany). *Res. Exp. Med. Berl.)* 168(3):199-201; 1976.

The possible prophylactic effect of somatostatin on ulcer formation was investigated in rats. Ten rats received somatostatin (100 mEq, s.c.) before and 3 and 6 hr after the administration of 9 hr of stress (restraint). All of 13 untreated control rats showed multiple gastric ulcers following stress, the mean total ulceration area for each rat being 16.67 ± 1.86 mm^2 and the ulcer index being 100%. Eight treated rats had no ulcers. The mean total ulceration area was reduced to 1.20 ± 1.09 mm^2 ($p<0.001$), and the ulcer index was reduced to 20% ($p<0.001$) in the treated rats that developed ulcers. There was also a significant reduction in the size of the ulcers in the treated animals. The results demonstrate that somatostatin protects against stress ulceration in the rat.

DIAGNOSTIC PROCEDURES

164 RELIABILITY OF CHEMICAL TESTS FOR FECAL OCCULT BLOOD IN HOSPITALIZED PATIENTS.

Eng.) Morris, D. W.; Hansell, J. R.; Ostrow, J. D.;
ee, C. S. (Rutgers Medical Sch., Piscataway, NJ
8854). *Am. J. Dig. Dis.* 21(10):845-852; 1976.

he reactions of three chemical spot tests for fecal
ccult blood were compared with the "true" blood
oss, as determined by stool radioassay, in 39 pa-
ients with suspected gastrointestinal bleeding, fol-
owing the i.v. injection of ^{51}Cr-labeled RBC.
uaiac reagent and orthotolidine (Hematest®) tablets
ere extremely sensitive, but yielded false-positive
eaction rates of 72% and 76%, resp., on the 240
tool specimens compared. A modified guaiac test
Hemoccult®) exhibited a false-positive rate of
2%. Of the 27 patients entering the study due
o positive guaiac or orthotolidine screening
ests, 17 (63%) were not bleeding. Modified
uaiac, approximately one-fourth as sensi-
ive as guaic and orthotolidine, could miss
esions with low rates of bleeding unless multiple
tools were tested. While barium had no effect,
ron therapy or laxatives tended to lower both
alse-positive and false-negative reactions for all
eagents. A positive modified guaiac test usually
ndicated significant gastrointestinal bleeding and
ppears to be the test of choice, provided at least
hree stools are tested to minimize false-negative
esults.

165 THE APPLICATION OF ENDOSCOPIC LUGOL'S SOLUTION SPRAYING METHOD FOR THE DIAGNOSIS
THE ESOPHAGITIS (FOR THE FOLLOW-UP OBSERVATION OF
UTE SEVERE ESOPHAGITIS).

(Eng.) Akasaka, Y.;
imoto, K.; Kawai, K.; Toriie, S.; Okuda, J.; Kubato,
; Ida, K. (Kyoto Prefectural Univ. Medicine, Kyoto,
apan). *Endoscopy* 8(3):142-146; 1976.

e endoscopic Lugol spraying method was used to
udy the healing process of acute severe esophagitis
148 patients. During acute esophagitis, endoscopy
evealed diffuse erosion or ulceration and scattered
ongested hemorrhagic areas in the lower third of the
sophagus. Normal areas had a "fine wrinkle" surface
attern. The lesions stained light yellow with
ugol, whereas normal areas were dark brown. The
egree of healing could be estimated by the recovery
staining in the affected areas. Healing began
ithin 14 days, when small epithelial islets with
rregular "fine wrinkles" appeared. Complete healing
as observed between 3 and 9 weeks.

166 EVALUATION OF THE INTRAEPITHELIAL LYMPHOCYTE COUNT IN THE JEJUNUM IN CHILDHOOD
TEROPATHIES.

(Eng.) Mavromichalis, J.; Brueton,
J.; McNeish, A. S.; Anderson, C. M. (Inst. Child
ealth, Univ. Birmingham, Birmingham, England). *Gut*
(8):600-603; 1976.

erial changes in the intraepithelial lymphocyte
ounts of children with a small intestinal entero-
athy were determined in 131 jejunal mucosal biopsies.
e small intestinal enteropathies arose from a varie-
of causes, including celiac disease (untreated, after gluten withdrawal, and during subsequent challenge), giardiasis, cow's milk protein intolerance, and "intractable diarrhea." The counts were compared with those from the biopsies of 29 children referred for investigation, but without gastrointestinal disease, and of 34 healthy siblings of children with celiac disease. The mean count of 12 children with untreated celiac disease (68 ± 19/100 epithelial cells) was significantly greater than that in the two normal groups (15 ± 4 and 17 ± 8/100 cells, resp., $p<0.001$), and the count dropped in the celiac patients after gluten withdrawal (25 ± 4/100 cells). Lymphocytic infiltration of the epithelium increased rapidly during gluten challenge in such children, while no change was seen in those children proven ultimately not to have celiac disease. In the other enteropathies, the range of counts was wide, overlapping with both normal and celiac groups and indicating the nonspecificity of lymphocytic infiltration of the gut epithelium. The results demonstrate that lymphocyte infiltration of the jejunal epithelium is increased in both adults and children with untreated celiac disease.

2167 A DOUBLE BLIND CROSSOVER STUDY OF METOCLOPRAMIDE VERSUS PLACEBO FOR FACILITATING PASSAGE OF MULTIPURPOSE BIOPSY TUBE.

(Eng.) Christie, D. L.; Ament, M. E. (Children's Orthopedic Hosp. and Medical Center, Seattle, WA). *Gastroenterology* 71(5):726-728; 1976.

The value of metoclopramide (M) in facilitating the passage of a multipurpose biopsy tube and capsule into the small intestine was investigated in a double blind, crossover study in 34 subjects. Five subjects withdrew from the study after one intubation. M (10 mg, i.v.) decreased intubation time to a mean of 10.4 ± 1.5 min ($p<0.05$) in 20 volunteers who were successfully intubated to the ligament of Treitz after both M and placebo (sodium metabisulfite, 2 ml); the intubation time after the administration of placebo was 16.8 ± 1.7 min. Of the remaining nine subjects who could be intubated, eight were intubated to the ligament of Treitz after M, but not after placebo ($p<0.01$). Among the 29 intubated volunteers, 22 were successfully intubated by 15 min when M was given, but only 9 of the 29 could be intubated in 15 min with placebo ($p<0.001$). Nine subjects experienced minor side-effects after receiving M. This study demonstrates that M is superior to placebo in decreasing the intubation time of a small intestinal biopsy capsule and is primarily useful in patients who may not otherwise be successfully intubated.

2168 THE NEONATAL COLON: AN ANATOMIC APPROACH TO PLAIN FILMS.

(Eng.) Kleinman, P. K.; Winchester, P.; Meyers, M. A.; Abbott, G. (Natl. Naval Medical Center, Bethesda, MD 20014). *Am. J. Roentgenol.* 128(1):61-64; 1977.

Factors involved in the identification of the neonatal colon in plain films are reviewed, and approaches to colon identification were applied in a retrospective examination of the plain abdominal films of eight cases of known distal colonic obstruction in newborns. It has been confirmed that haustral folds are well developed at birth; in one study, colonic haustrations were demonstrated in 81 of 105 neonates by barium enema examination. Prominent haustrations are evident in the transverse colon and, to a lesser extent, in the descending colon. Identification of the colon can be further enhanced if a gas-filled loop of bowel can be recognized within a characteristic course and relationship to other abdominal structures. Using these two criteria of colon identification, the colon was clearly identified on three of five cases of imperforate anus and in two of three cases of Hirschsprung's disease. Colon identification was most likely if abdominal films in multiple projections were obtained with the onset of abdominal distension. With progressive distension and atony of large and small bowel, confusing superimposition of shadows occurred. However, it is apparent that colonic gas can be identified in a significant number of infants with low colonic obstruction.

2169 FIBEROPTIC ENDOSCOPY AND UPPER GASTROINTESTINAL SERIES: COMPARATIVE ANALYSIS IN INFANTS AND CHILDREN. (Eng.) Gyepes, M. T.; Smith, L. E.; Ament, M. E. (Univ. California Sch. Medicine, Los Angeles, CA 90024). *Am. J. Roentgenol.* 128(1): 53-56; 1977.

The results of fiberoptic endoscopy were compared with those of upper gastrointestinal series in 75 infants and children. Agreement between the two studies was obtained in 49 cases (65.3%) and disagreement, in 26 (34.6%). The original radiologic reports were negative, but the endoscopic reports were positive in 17 cases (22.6%), while the converse was true in 9 cases (12%). Superficial lesions in the esophagus, stomach, and duodenum were most often missed by conventional barium studies, while false-positive radiologic reports occurred in the duodenum. There were only two minor complications, both mucosal tears, which did not require surgery; both appeared to occur because of inadequate sedation. The results suggest that fiberoptic endoscopy is a more accurate tool in the diagnosis of superficial mucosal lesions in children than conventional barium studies. However, the high rate of detection of nonsuperficial lesions by radiographic methods is encouraging.

2170 ASSESSMENT OF THE ACCURACY OF DOUBLE CONTRAST GASTRODUODENAL RADIOLOGY. (Eng.) Laufer, I. (Hosp. Univ. Pennsylvania, 34th and Spruce St., Philadelphia, Pa 19104). *Gastroenterology* 71 (5):874-878; 1976.

The accuracy of routine double contrast gastroduodenal radiology, based on experience with 1,500 consecutive examinations was assessed. The value of this technique was illustrated by the demonstration of subtle abnormalities, such as erosions, linear ulcers, and ulcer scars, which are usually not demonstrated by the standard barium study. Two hundred twenty-five of these patients were also examined by endoscopy; radiological errors were found in 7%. This represents a marked improvement over the standard barium study in which errors may occur in 18-33% In the last 128 patients, a confidence level ranging from 3 (certainty) to 1 (uncertain) was assigned to the radiological diagnosis before endoscopy. The majority of radiological errors occurred in the few studies given the lowest confidence level. These fin ings indicate that the double contrast study of the stomach and duodenum can be a very accurate examination and that endoscopy can be applied more selectively to patients with inconclusive double contrast studies.

2171 LINEAR AND ROD-SHAPED PEPTIC ULCERS. (Eng.) Poplack, W.; Paul, R. E., Jr.; Goldsmith, M.; Matsue, H.; Bloom, S.; Moore, J. P.; Norton, R. A. (New England Medical Center, 171 Harrison Ave., Boston, MA 02111). *Radiology* 122(2):317-319; 1977.

The results of approximately 1,500 upper gastrointestinal series performed by the pharmacologically-aided, double-contrast technique were reviewed to demonstrate that active and healing ulcers can be diagnosed by this technique. Peptic ulcers were divided into one of six classifications, according to shape and size (i.e., tiny, linear, rod, ovoid, round, and irregular). During a 6-month period, 13 linear and rod-shaped ulcers were observed. Gastric relaxation and good mucosal coating were necessary to detect ulcers of this shape. Linear ulcers were found to occur both as initial ulcer forms and a stages in healing of ulcers that started as irregular, round, or ovoid forms. Several illustrations are presented. The results demonstrated that no particular clinical manifestations could be attributed to linear ulcers or other specific ulcer forms.

2172 HEPATIC ABSCESS: DIAGNOSIS IN THE ADULT BY TOTAL BODY OPACIFICATION. (Eng.) Morin, M. E.; Baker, D. A.; Marsan, R. E. (Veterans Admin. Lakeside Hosp., 33 E. Huron St., Chicago, IL 60611). *JAMA* 236(14):1607-1608; 1976.

The cases of two patients in whom hepatic abscesses were demonstrated by total body opacification (TBO) are presented. The first patient, a 55-yr-old man, presented with a 1-month history of diarrhea, anorexia, malaise, and increasing abdominal girth. A ^{99m}Tc sulfur colloid liver scan showed a focal defect in the posterosuperior aspect of the right lobe, and a ^{67}Ga scan suggested either an abscess or a hepatoma. A routine preoperative excretory urogram was modified to include tomograms of the liver during the TBO phase. The lesion was shown to be hypovascular, suggesting an abscess, and this was confirmed by B-mode gray-scale ultrasonography. The serum hemagglutination for *Entamoeba histolytica* was strongly positive, and the symptoms resolved in response to metronidazole therapy. The second patient, a 46-yr-old man, presented with right flank and upper right quadrant pain, nausea, vomiting, and fever. The TBO phase of an excretory urogram showed a multiloculated, thick-walled intrahepatic lucency, which was diagnosed preoperatively as an abscess. The abscess replaced 20% of the right lobe, and pus cultures grew *Fusobacter-*

ium nucleatum and *Peptostreptococcus micros*. TBO is helpful in the preoperative diagnosis of abdominal masses.

2173 A COMPARISON OF ANGIOGRAPHY AND SCINTIGRAPHY AS DIAGNOSTIC METHODS FOR AMEBIC LIVER ABSCESS. (Eng.) Lundberg, Y. (Roslagstulls sjukhus, Box 5901, S-114 89 Stockholm, Sweden). *Scand. J. Infect. Dis.* 8(4):263-265; 1976.

Angiography was compared with scintigraphy in the diagnosis of amebic liver abscess in 12 patients with amebiasis. In five patients, scintigraphy indicated a liver abscess; this diagnosis was supported by colloidal radioactive gold isotope angiography in three patients. The abscess was seen in the scintigram as a defect in the radionuclide uptake of the liver and in the angiogram, as an area devoid of vessels and of defective contrast loading. Although the number of patients is too small to draw definite conclusions, scintigraphy may be slightly superior to angiography in the diagnosis of amebic liver abscesses.

2174 GRAY SCALE ULTRASONIC CHOLECYSTOGRAPHY: A COMPARISON WITH CONVENTIONAL RADIOGRAPHIC TECHNIQUES. (Eng.) Leopold, G. R.; Amberg, J.; Gosink, B. B.; Mittelstaedt, C. (Univ. Hosp., 225 W. Dickinson St., San Diego, CA 92103). *Radiology* 121(2):445-448; 1976.

A prospective study was carried out to assess the accuracy of gray scale ultrasonography in the evaluation of cholelithiasis. One hundred eleven patients with nonvisualization on first-day p.o. cholecystography underwent ultrasonic cholecystography, and the results were compared with subsequent second-day visualization or surgical findings. Among 75 patients in whom sufficient data were present to assess the accuracy of the method (i.e., satisfactory second-day cholecystogram or surgical evidence), ultrasound correctly diagnosed gallstones in 68. Gallstones were identified as single- or multiple-echo dense structures lodged in the most dependent portion of the gallbladder. Shadowing was often the key feature that allowed the detection of biliary calculi, and this effect was obvious only when a sectoring technique was used to perform the scan. Only six gallbladders could not be visualized ultrasonically, and all subsequently proved to contain gallstones. Twenty-four of the 75 patients had inadequate radiographic visualization. Among the 52 patients with adequate radiographic visualization, 32 were considered to have normal gallbladders; in 31 of these, ultrasound was also normal. The remaining case was considered to be a false-positive ultrasonographic diagnosis. The overall accuracy of ultrasonic cholecystography was 91%. It is concluded that improved ultrasonic technique is of considerable value in investigating the nonvisualized gallbladder.

2175 HEPATOSCINTIGRAPHY, ARTERIOGRAPHY, AND ULTRASONOGRAPHY IN PREOPERATIVE DIAGNOSIS OF CHOLEDOCHAL CYST. (Eng.) Piyachon, C.; Poshyachinda, M.; Dhitavat, V. (Chulalongkorn Hosp., Bangkok, Thailand). *Am. J. Roentgenol.* 127(3):520-523; 1976.

The case of a 32-yr-old woman in whom a choledochal cyst was correctly diagnosed preoperatively by hepatoscintigraphy, arteriography, and ultrasonography is presented. The patient presented with a 20-day history of jaundice, abdominal pain, fever, and an abdominal mass. The upper gastrointestinal examination showed an extrinsic pressure effect on the body of the stomach, with displacement to the left and caudal, and barium enema examination demonstrated depression of the hepatic flexure and proximal transverse colon. Liver scintigraphy with ^{198}Au showed marked enlargement of the liver, with a large space-occupying lesion in the anteromedial aspect of the right lobe and another smaller defect in the left lobe. Abdominal aortography and celiac, superior mesenteric, and selective hepatic arteriography established that the lesion was cystic, rather than a malignancy. These techniques demonstrated anterior displacement, stretching, and elongation of the common hepatic and gastroduodenal arteries. The right hepatic artery was elevated and stretched. Due to marked dilatation of the hepatic ducts secondary to impacted stones, the displacement of hepatic arterial branches and lucencies in the parenchymal phase were markedly prominent. Findings on B-mode ultrasonography correlated well with the angiographic findings in the demonstration of the cyst and dilated hepatic ducts. Accumulation of radioactivity in delayed scintigram with the use of ^{131}I rose bengal indicated that the lesion was a bile-containing structure. Complementary information from these studies is helpful in the diagnosis of choledochal cyst. The demonstration of a sonolucent mass in the epigastrium with small cystic lesions in the liver is suggestive of the diagnosis.

2176 FALSE-POSITIVE LIVER SCAN CAUSED BY ANOMALOUS QUADRATE LOBE AND RIGHT PORTAL BRANCH. (Eng.) Suzuki, K.; Okuda, K.; Musha, H.; Nakajima, Y.; Kimura, K.; Kuniyasu, Y. (Chiba Univ. Sch. Medicine, Chiba City [280], Japan). *Acta Hepatogastroenterol.* 24(1):27-29; 1977.

The case of a patient with a false-positive liver scan caused by anatomical abnormalities and dilatation of the right portal branch is presented. The patient, a 44-yr-old man, had hepatomegaly, splenomegaly, spider angiomata, and abnormal liver function tests. A ^{99m}Tc-phytate liver scan demonstrated a clearly demarcated defect in the hilar area along the inferomedial edge of the right lobe. Laparoscopy revealed a tongue-like protrusion in the inferior surface of the quadrate lobe to the left of the gallbladder bed. Percutaneous transhepatic portography showed an anomalous division of the portal vein and moderate dilatation of the right portal branch.

2177 DIAGNOSTIC VALUE OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN BILIODIGESTIVE ANASTOMOSES. (Eng.) Papp, J.; Tulassay, Z.; Bielawski, J.; Hajos, E.; Kollin, E.; Pfeiffer, I. (Semmelweis Univ. Medical Sch., H-Budapest, Hungary). *Acta Hepatogastroenterol.* 24(1):41-43; 1977.

The diagnostic value of endoscopic retrograde cholangiopancreatography (ERCP) in biliodigestive anastomoses was studied in 62 patients. In 54 patients, ERCP was carried out to clarify the abnormality underlying biliary obstruction. In the majority of cases, opacification was carried out via the stoma (51 patients); catheterization of the papilla was also necessary in 25 cases. The bile duct was visualized in 55 cases, and the pancreatic duct was seen in 21 cases. Catheterization was unsuccessful in two cases. ERCP revealed a pathological finding in 75% of the patients. ERCP appears to be a reliable diagnostic method in patients with biliodigestive anastomosis.

2178 THE SIGNIFICANCE OF PANCREATIC DUCTAL OBSTRUCTION IN DIFFERENTIAL DIAGNOSIS OF THE ABNORMAL ENDOSCOPIC RETROGRADE PANCREATOGRAM.

(Eng.) Rohrmann, C. A., Jr.; Silvis, S. E.; Vennes, J. A. (Univ. Washington Sch. Medicine, Seattle, WA 98195). *Radiology* 121(2):311-314; 1976.

Fifty pancreatograms showing incomplete opacification of the pancreatic duct in patients with proved pancreatic status were reviewed to gain information on the differential diagnosis of the wide variety of pancreatic diseases showing this abnormality. Seven patients had normal pancreatic function. The final diagnosis in the remaining patients was pseudocyst in 15, neoplasm in 15, chronic pancreatitis in 8, acute recurrent pancreatitis in 3, and abscess in 2. The site of obstruction among the patients with pseudocyst occurred most commonly in the pancreatic head and body (87%). When the point of termination was visualized, it usually had no specific character. In 25% of the cases, the terminus was not visualized, usually being obscured by the cyst. All pseudocysts were greater than 2 cm in diameter. In the patients with a neoplasm, the terminus was tapered, destructive irregular, or eccentric in 73% and nonspecific or blunt in the remainder. The site of obstruction was most commonly in the pancreatic head and to the right of the spine (60%). In the patients with a normal pancreas, the terminus was uniformly nonspecific and occurred at the point where the duct traverses the spine. Obstruction occurred most commonly in the body and tail (87%) in patients with chronic pancreatitis; the point of termination was uniformly blunt or nonspecific. The results suggest that the differential diagnosis of abnormal endoscopic retrograde pancreatograms is facilitated by accurate evaluation of the ductal and extraductal characteristics, particularly the ductal detail at the point of termination.

2179 INCREASED PANCREATIC VOLUME IN FRONTAL RADIOGRAPHY OF THE STOMACH.

(Por.) Parra, O. M.; Saad, W. A.; Gutierez, F. (Clin. Cir., Hosp. Munic. do Tatuape, Tatuape, SP, Brazil). *Rev. Assoc. Med. Bras.* 21(8):245-247; 1975.

The diagnostic value of frontal radiography of the stomach in the detection of increased pancreatic volume was analyzed retrospectively using radiographs of eight patients with clinically confirmed pancreatic pseudocysts (6), chronic pancreatitis (1), and cancer of the head of the pancreas (1). Classic radiological signs of pancreatic enlargement were not detected at the initial examination, except in one patient with large pseudocysts of the head and tail of the pancreas. This patient showed radiological signs of compression, which were diagnosed as gastric polyps and not even mentioned in the radiological report. Re-examination of the radiographs showed no signs of dislocation or compression in five patients, including one with large tumor of the pancreas. The remaining three patients showed central compression images of variable size and shape. These usually had vague outlines and were located on a clear background; darkening of the gastric folds was noted, probably due to the distention of the mucosa. A more accurate analysis of frontal radiographs of the stomach may result in a better detection of pancreatic enlargements. Radiography in dorsal decubitus--with barium or double contrast--gives much better results than frontal radiography.

GASTROINTESTINAL DISEASES

ESOPHAGUS

2223 VALUE OF ESOPHAGEAL MANOMETRIC STUDIES IN THE GASTROESOPHAGEAL REFLUX OF INFANCY. (Eng.) Euler, A. R.; Ament, M. E. (Univ. California Sch. Medicine, Los Angeles, CA 90024). *Pediatrics* 59(1):58-61; 1977

Esophageal manometric studies were carried out in 15 infants with symptoms of gastroesophageal reflux (GER) to determine if these procedures are helpful in identifying patients who require surgery. The symptoms included chronic postprandial vomiting, beginning during the first 7 days of life. Esophagograms were carried out in 14 infants; hiatal hernia was diagnosed in 2, reflux in 4, and stricture in 1. Esophagoscopy in eight subjects revealed spontaneous friability of the lower third of the esophagus in three infants and stricture in one; all patients with friability or stricture had histological documentation of esophagitis. All infants were placed on a regimen of frequent thickened feedings and were kept in an upright position 24 hr per day for 3 weeks. Nissen fundoplications were performed in the six infants who did not respond to this treatment. Their mean lower esophageal sphincter pressure was 12.7 mm Hg, while that of the nine infants who did well on the medical regimen was 19.6 mm Hg ($p < 0.001$). The results suggest that esophageal manometric studies should be included in the evaluation of all infants with symptoms of chronic GER.

2224 STIMULATORY EFFECT OF METOCLOPRAMIDE ON THE ESOPHAGUS AND LOWER ESOPHAGEAL SPHINCTER OF PATIENTS WITH PSS. (Eng.) Ramirez-Mata, M.; Ibanez, G.; Alarcon-Segovia, D. (Instituto Nacional de la Nutricion, Av. San Fernando y Viaducto Tlalpan, Mexico 22, D.F., Mexico). *Arthritis Rheum.* 20(1): 30-34; 1977.

Because metoclopramide has been shown to stimulate gastrointestinal motility, the effect of i.v. metoclopramide (20 mg) on the sphincter pressure and esophageal motility were tested in 14 patients with esophageal dysfunction due to progressive systemic sclerosis (PSS). Isotonic saline similarly injected in a control period in seven patients showed no effect. None of the patients had a detectable pressure zone at the sphincteric area in basal conditions, but a pressure zone appeared in seven patients after metoclopramide injection. Metoclopramide also caused the appearance of pressure waves in 5 of 11 patients who had aperistalsis, and caused up to a threefold increase in the amplitude of the pressure waves in the 3 patients who had hypomotility of the esophagus. Because metoclopramide can be used p.o., it may be helpful for the relief of both dysphagia and acid regurgitation.

STOMACH

2237 INTRAMURAL GASTROINTESTINAL HEMORRHAGE: CLINICAL AND RADIOGRAPHIC MANIFESTATIONS. (Eng.) Balthazar, E. J.; Einhorn, R. (New York Medical Coll.-Metropolitan Hosp. Center, 1901 First Ave., New York, NY 10029). *Gastrointest. Radiol.* 1(3):229-239; 1976.

The clinical and radiographic manifestations of intramural gastrointestinal hemorrhage, based on the analysis of 20 cases affecting different segments of the gastrointestinal tract, are presented, together with a review of the literature. The pathologic process is induced principally by anticoagulant therapy, bleeding diathesis, or abdominal trauma and occurs as a localized, well-defined, intramural mass or as a more diffuse segmental involvement. The clinical features are nonspecific and can vary from mild crampy abdominal pain to severe shock. Other manifestations include rebound tenderness, muscle guarding, and small bowel obstruction. The duodenum and small bowel are the most frequent sites of involvement. The intestinal mucosal folds may be prominent, stretched, and sharply defined or completely effaced, accompanied by a smooth narrowing. There is rapid clinical and radiographic remission with conservative therapy. Intestinal perforations and fibrotic strictures resulting in small bowel obstruction are rare, being observed only in the post-traumatic variety.

2238 ANTRAL GASTRIN CONCENTRATION IN PATIENTS WITH VAGOTOMY AND PYLOROPLASTY. (Eng.) Hughes, W. S.; Hernandez, A. J. (Univ. Texas Medical Branch, Galveston, TX 77550). *Gastroenterology* 71(5):720-722; 1976.

To determine whether an increase in antral gastrin concentration could be a factor in postvagotomy hypergastrinemia, antral gastrin concentration was measured in endoscopic forceps biopsy specimens of prepyloric mucosa in patients with vagotomy and pyloroplasty, duodenal ulcer patients, and nonulcer patients. The antral gastrin concentration in vagotomy and pyloroplasty patients (35.5 ± 4.1 ng gastrin/mg tissue), was significantly greater ($p<0.01$) than the antral gastrin concentration in duodenal ulcer patients (13.0 ± 2.4 ng/mg), and that in controls (14.8 ± 3.1 ng/mg). Basal and meal-stimulated serum gastrin levels in vagotomy and pyloroplasty patients were also significantly greater ($p<0.05$) than gastrin levels in either duodenal ulcer patients or controls. Acid secretion rates were not significantly correlated with serum or antral gastrin concentrations in the patient groups. The finding of high antral gastrin concentration in patients with vagotomy and pyloroplasty is consistent with the hypothesis that a high concentration of tissue gastrin accounts, at least in part, for the high serum gastrin levels. The rate of gastrin synthesis, as well as the rate of gastrin release, is increased in these patients.

Peptic Ulcers

2280 ENDOSCOPIC ELECTROCOAGULATION OF UPPER GASTROINTESTINAL HEMORRHAGE. (Eng.) Papp, J. P. (2500 Oakwood Drive S.E., Grand Rapids, MI 49506). *JAMA* 236(18):2076-2079; 1976.

The results of endoscopic electrocoagulation performed on 40 occasions in 38 patients, with bleeding gastrointestinal lesions, are presented. Cessation of bleeding was achieved in 95%. Fifteen gastric ulcers, 14 duodenal ulcers, 6 Mallory-Weiss tears, 1 gastric varix, 1 hemorrhagic antral gastritis, and 1 esophageal ulcer were successfully electrocoagulated. Three duodenal and three gastric ulcers rebled. One duodenal ulcer and one gastric ulcer were successfully reelectrocoagulated. Failure to stop bleeding by electrocoagulation occurred in one Mallory-Weiss tear and one duodenal ulcer. There was no morbidity or mortality attributed to endoscopic electrocoagulation. A retrospective cost analysis showed that the cost of hospitalization was less in patients treated by electrocoagulation. Patients so treated were hospitalized 1.5 days longer than surgically treated patients with bleeding, but less than patients treated medically. This series suggests that endoscopic electrocoagulation should be used in bleeding gastrointestinal lesions and that surgery should be carried out only if this technique fails to achieve hemostasis.

281 A REPRODUCIBLE ANIMAL MODEL OF ACUTE BLEEDING ULCER--THE "ULCER MAKER." (Eng.) rotell, R. L.; Silverstein, F. E.; Piercey, J.; ennis, M.; Sprake, W.; Rubin, C. E. (Dept. Medicine, niv. Washington, Seattle, WA 98195). *Gastroenterology* 71(6):961-964; 1976.

multipurpose suction biopsy tube that has been modfied to make acute gastric ulcers by enlarging the apsule and its biopsy orifice is described, and the iameter and depth of experimental ulcers made with his instrument in dogs were standardized. The rate f bleeding, with and without heparinization, was also valuated. The most reproducible ulcers, in terms of ize and degree of bleeding, were obtained from the undal gland area (as opposed to the antrum) at -14 ches Hg suction held for 1 sec, using an 8.1-mm diaeter internal obturator. All 58 ulcers made in this anner in eight mongrel dogs extended into the submusa, but not into the muscularis externa. The ulcers easured 9.38 ± 1.27 mm in diameter and 1.54 ± 0.31 mm depth. Five of twelve gastric ulcers in unheparized dogs stopped bleeding spontaneously. The rate bleeding was variable during the first 3 min in parinized dogs (range, 0.3-22.4 ml), but 33 of the ulcers had an initial 3-min bleeding rate between and 9 ml. These ulcers could be classified accordg to their initial 3-min bleeding rate into three tegories: mild (<3 ml, 15 ulcers), moderate -<6 ml, 22), and severe (>6 ml, 21). During min observation of 16 ulcers, bleeding rate deeased spontaneously a median of 55%. No ulcer opped bleeding during a 70-min observation period. ing this model, nonsurgical modalities for the treatment of upper gastrointestinal bleeding can be compared in a controlled manner.

2282 EFFECTS OF ETHYL ALCOHOL ON THE ADENOSINE 3', 5'-MONOPHOSPHATE SYSTEM OF THE HUMAN GASTRIC MUCOSA. (Eng.) Karppanen, H.; Puurunen, J.; Kairaluoma, M.; Larmi, T. (Dept. Pharmacology, Univ. Oulu, SF-90 220 Oulu 22, Finland). *Scand. J. Gastroenterol.* 36(4):603-607; 1976.

In vitro studies were carried out to determine whether the cyclic AMP system is involved in the changes of gastric acid secretion induced by different concentrations of p.o. ethyl alcohol in man. Gastric mucosa was obtained from patients operated on for gastric or duodenal ulcers. Five percent ethanol (volume/volume) or less stimulated the activity of adenylate cyclase and induced a dose-dependent rise of the gastric mucosal content of cyclic AMP. However, 10% ethanol increased the activity of adenylate cyclase, but did not affect the gastric mucosal content of cyclic AMP. Five or ten percent ethanol inhibited the activity of cyclic AMP phosphodiesterase in a competitive manner. Reports in the literature indicate that p.o. ethanol stimulates the output of gastric acid at low, but not at higher, concentrations; the present results are consistent with the concept that the stimulatory effect of ethanol on the output of acid is mediated by an increase of the content of cyclic AMP in the gastric mucosa.

2283 ANTACID AND PLACEBO PRODUCED SIMILAR PAIN RELIEF IN DUODENAL ULCER PATIENTS. (Eng.) Sturdevant, R. A. L.; Isenberg, J. I.; Secrist, D.; Ansfield, J. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 72(1):1-5; 1977.

A comparison of an antacid and a placebo in relieving duodenal ulcer pain in patients with duodenal ulcers and epigastric pain is presented. One study on ten hospitalized patients receiving randomized doses of antacid or placebo over 5 days showed no significant difference in the degree of relief of pain, the time required to achieve relief, or the duration of the relief, as evaluated by the patients. A second study on 20 patients receiving a single massive dose of antacid or placebo also failed to reveal any significant difference in effectiveness of the two types of treatment. The authors suggest that factors other than acid neutralization may be important in the relief of acute duodenal ulcer pain, but note also that experiments on a larger patient population may reveal a statistically significant difference in the types of treatment because antacid treatment was arithmetically more effective.

2284 THE EFFECT OF 15 (R) 15 METHYL PROSTAGLANDIN E_2 ON GASTRIC ACID SECRETION IN DUODENAL ULCER PATIENTS. (Eng.) Chen, F. W. K.; Teck, H. S.;

Karim, S. M. N. (Singapore General Hosp., Republic of Singapore). *Prostaglandins* 13(1):115-124; 1977.

The prostaglandin analogue 15-(R)-15-methyl prostaglandin E_2 (15-R-PGE_2) was administered p.o. to 24 duodenal ulcer patients to investigate its effect on basal and pentagastrin-stimulated maximal acid secretion. All patients fasted overnight and were given either a water placebo or 150 μg of the analogue. Basal acid secretion was significantly decreased from 5.9 ± 1.5 mEq/hr to 2.1 ± 0.6 mEq/hr ($p<0.05$) by the prostaglandin analogue. The maximal acid output was also decreased by treatment with the prostaglandin analogue, from 32.1 ± 1.6 mEq/hr to 20.6 ± 1.5 mEq/hr ($p<0.001$). Unlike the basal secretory volume, the maximal secretory volume was significantly reduced after administration of the analogue ($p<0.001$). These results are similar to those observed earlier in healthy subjects, except for the effect upon the maximal secretory volume, and suggest that 15-R-PGE_2 may be useful in duodenal ulcer healing.

2285 THE EFFECT OF ANTRAL DISTENSION ON ACID SECRETION AND PLASMA GASTRIN IN DUODENAL ULCER PATIENTS.

(Eng.) Bergegardh, S.; Nilsson, G.; Olbe, L. (Sahlgren's Hosp., S-413 45 Gothenburg, Sweden). *Scand. J. Gastroenterol.* 11(5):475-479; 1976.

The effect of antral balloon distension on gastric acid secretion and on plasma gastrin concentration was studied in 8 duodenal ulcer patients. Antral distention (150 ml) resulted in a significant ($p<0.05$) increase in acid secretion from 5.0 ± 1.2 mEq/45 min during the basal period to 11.1 ± 2.4 mEq/45 min. The latter value is equivalent to about 30% of the peak acid response (13.5 ± 1.4 mEq/15 min) to pentagastrin stimulation (90 μg/hr for 45 min followed by 300 μg/hr for 45 min, i.v.). No significant differences were observed between fasting (51 ± 7 pg/ml) or basal (47 ± 6 pg/ml) plasma gastrin and plasma gastrin values during antral distension (52 ± 6 pg/ml at 150-ml antral distension). Under conditions of intragastric neutralization (Sorensen's phosphate buffer, pH 8.3), antral distension (150 ml) again significantly ($p<0.05$) increased acid secretion from 3.2 ± 0.4 mEq/45 min during the basal period to 11.1 ± 1.9 mEq/45 min. A significant difference ($p<0.01$) also existed between acid output at 150-ml antral distension and the postdistension value (5.3 ± 0.8 mEq/45 min). The mean peak acid output to pentagastrin stimulation was 12.3 ± 1.3 mEq/15 min. Plasma gastrin concentrations measured during antral distension (90 ± 9 pg/ml at 150-ml distension) did not significantly differ from those during the basal period (87 ± 9 pg/ml) or in the fasting state (86 ± 10 pg/ml). Basal acid secretion did not significantly change with the addition of buffer for neutralization (3.2 ± 0.4 mEq/min without and 6.2 ± 1.2 mEq/45 min with buffer). These results suggest that the acid response to antral distension in duodenal ulcer patients is evoked without contribution of the gastrin mechanism and that the acid response is probably mediated via a pyloro-oxyntic reflex.

2286 SELECTIVE LOSS OF PARIETAL CELLS IN THE GASTRIC REMNANT FOLLOWING ANTRAL RESECTION.

(Eng.) Sippónen, P.; Hakkiluoto, A.; Kalima, T. V.; Siurala, M. (Central Lab. Pathology, Univ. Helsinki, Haartmaninkatu, 3, SF-00290 Helsinki 29, Finland). *Scand. J. Gastroenterol.* 11(8):813-816; 1976.

The mucosa of the gastric remnant of 41 patients who had undergone antral resection 17-18 yr previously for peptic ulcer was studied histologically. A normal mucosa was observed in only one patient. Superficial or atrophic gastritis was seen in 27 patients, while the remaining 13 had "selective parietal cell loss." This was characterized by a marked decrease in the number of parietal cells, without any appreciable increase in the number of round cells; the zymogenic chief cells also showed no decrease in number. The foveolar part of the mucosa was hyperplastic, with corkscrew-like structures and hyperplastic mucus-secreting cells. The fasting serum gastrin levels measured in 20 patients were within normal limits. Selective parietal cell loss is thought to reflect a lack of trophic action on parietal cells exerted by gastrointestinal hormones, such as gastrin.

2287 ALTERED PANCREATIC FUNCTION AFTER PROXIMAL GASTRIC VAGOTOMY IN MAN.

(Eng.) Berstad, A.; Roland, M.; Petersen, H.; Liavag, I. (Aker Hosp., Oslo-5, Norway). *Gastroenterology* 71(6):958-960; 1976.

The secretion of bicarbonate into the duodenum in response to stepwise increasing doses of secretin (0.078, 0.23, 0.7, and 2.1 U/kg/hr) was investigated in 11 duodenal ulcer patients before and about 1.5 yr after proximal gastric vagotomy. After the vagotomy, the mean output of bicarbonate in response to the two lowest doses of secretin increased from 2.2 to 3.7 mmol per 30 min in response to 0.078 U/kg/hr and from 6.6 to 9.8 mmol per 30 min in response to 0.23 U/kg/hr. The output of bicarbonate in response to the highest dose of secretin decreased from 20.3 mmol per 30 min before vagotomy to 16.5 mmol per 30 min after the vagotomy. The dose of secretin required for half-maximal stimulation decreased from 0.7 to 0.3 U/kg/hr. The calculated maximal bicarbonate response decreased from 27.8 to 17.7 mmol per 30 min. Thus, the bicarbonate-producing cells have an increased sensitivity to low doses of secretin, and the pancreas has a decreased bicarbonate secretory capacity after proximal gastric vagotomy.

2288 THE FUNCTION OF THE EXOCRINE PANCREAS AFTER EXOGENOUS AND ENDOGENOUS STIMULATION IN BILLROTH II PATIENTS.

(Eng.) Tympner, F.; Rosch, W.; Domschke, W.; Demling, L. (Medizinische Klinik mit Poliklinik der Universitat Erlangen-Nurnberg, Krankenhausstr. 12, 8520 Erlangen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(6):444-448; 1976.

To study the possible relation between pancreatic atrophy and post-Billroth II gastrectomy steatorrhea

he function of the exocrine pancreas was studied in
7 patients who had undergone Billroth II gastrec-
omy and in 60 healthy controls. A Lagerlof tube
as placed into the afferent loop endoscopically,
nd pancreatic function was studied after endogenous
timulation (Lundh test meal instillation through
he efferent loop for 60 min) and exogenous stimu-
ation with i.v. secretin (1 CU/kg) plus pancreozymin
l CU/kg). Bicarbonate production and enzyme secre-
ion were similar in the patients and controls dur-
ng endogenous stimulation. During exogenous stimu-
ation, the mean trypsin and chymotrypsin outputs in
he controls were significantly greater than those
n the patients. The results indicate that exocrine
ancreatic function in Billroth II gastrectomy pa-
ients is reduced in comparison with controls follow-
ng maximum stimulation with secretin-pancreozymin;
his is consistent with the previously reported mor-
hological changes in the pancreas of Billroth II
tients.

SMALL INTESTINE

2311 EFFECTS OF A FAT-REDUCED DIET ON THE FAECAL EXCRETION OF RADIOACTIVITY FOLLOWING ADMINISTRATION OF ^{14}C-CHOLIC ACID AND ON THE DUODENAL CONCENTRATION OF BILE SALTS IN PATIENTS WITH ILEAL DISEASE. (Eng.) Andersson, H. (Sahlgren's Hosp., Goteborg, Sweden). *Nutr. Metab.* 20(4):254-263; 1976.

Patients with ileal disease were subjected to high- versus low-fat diets to determine the effect of reduced fat intake on the fecal excretion of ^{14}C-labeled cholic acid (10 μCi, i.v.) and on the duodenal bile salt concentration. Twelve patients were first observed on a diet with 100 g of fat for 8-16 days, and then on a diet with 40 g of fat for 16-28 days. The abnormally high amounts of fecal radioactivity excreted by all patients on the high-fat diet (58-100%) were significantly lowered after exposure to the low-fat diet (0.2-94%, $p<0.005$). Subnormal duodenal bile salt concentrations were observed in patients with ileal disease on the high-fat diet, but sufficient data were not obtained for the low-fat diet. The bile salt concentrations were also much lower in patients with a functioning gallbladder on the high-fat diet after the evening meal than in the morning. This was not observed with the low-fat diet. The low-fat diet increased the bowel transit time in 7 of 12 patients, and decreased diarrhea in all patients. A reduction in fatty acids in the small intestine probably permits greater absorption of water, electrolytes, and bile salts, as well as a decreased emptying of the gallbladder, thus avoiding the loss of cholic acid and the clinical effect of diarrhea.

2312 INTERRELATIONSHIPS BETWEEN THE GASTROJEJUNAL MICROBIAL FLORA AND THE MORPHOLOGY OF THE JEJUNAL MUCOSA IN ACHLORHYDRIC ENTEROPATHY. (Rum.) Dobre, D.; Hurmuzache, E.; Dobre, V.; Dobrescu, G. (Institutul de medicina si farmacie, Iasi, Romania). *Rev. Med. Chir. Soc. Med. Nat. Iasi* 78(4):809-814; 1974.

The correlation between gastrojejunal bacterial flora and morphological aspect of the jejunal mucosa was studied in 40 patients with diarrheal syndrome and with achlorhydria confirmed by maximally stimulated gastric secretion (histamine test). Bacteria in the gastric juice (10^4-10^6 bacteria/ml, mostly enterobacteria, streptococci, enterococci, and bacteroides) were found in 95% of the patients, compared to sterile gastric juice found in 15 normochlorhydric control subjects. Bacterial presence in the jejunal juice (10^5-10^8/ml, mostly enterobacteria, enterococci, lactobacilli, bacteroides, clostridia, staphilococci, and veillonellae) were found in 93% of the patients, while it was absent in 72% of the controls. Jejunal biopsies revealed jejunitis in 26 patients. Diffuse jejunitis was the most frequent type, but superficial infiltrative and deep interstitial jejunitis were also found. Treatment with tetracycline (1.5 g/day x 8-10, p.o.) in 10/26 patients with confirmed diffuse jejunitis and a bacterial count of 10^6/ml resulted in jejunal sterility in 7 and low bacterial count (10^2-10^3/ml) in 3. Two weeks after the beginning of the treatment, endobiopsies revealed normal jejunal mucosa in six patients, while only superficial jejunitis persisted in four. Lesions of the jejunal mucosa in patients with achlorhydria are directly related to the bacterial flora, whose existence and population density are a function of the disturbances in the gastric pH.

2313 YERSINIA ENTERITIS AND ENTEROCOLITIS: GASTROENTEROLOGICAL ASPECTS. (Eng.)

Vantrappen, G.; Ponette, E.; Geboes, K.; Bertrand, P. (Akademisch Ziekenhuis St. Rafael, B-3000 Leuven, Belgium). *Gastroenterology* 72(2):220-227; 1977.

The clinical, radiological, and endoscopic aspects of *Yersinia enterocolitica* infections in man were studied in 37 adult patients observed over a 4-yr period. The diagnosis was based on isolation of the bacterium in all but one patient. Abdominal pain and diarrhea were the most prominent symptoms, occurring in 80% of the patients. A syndrome simulating appendicitis was observed in 40%. The duration of symptoms before diagnosis varied from 1 or 2 weeks in 32 patients to several months in 5. On radiological examination, the terminal ileum was involved over a distance of 10-20 cm in 21 of 24 patients. A coarse, irregular, or nodular mucosal pattern and pictures suggestive of ulcerations were the most prominent and early radiological signs. Endoscopic observations in 13 patients with marked diarrhea showed signs of colitis in 6 and aphthoid ulcers in 2 patients. On pathological examination, ulcerations and a nonspecific acute inflammatory cell infiltrate were observed. Although treatment with tetracycline or chloramphenicol resulted in the disappearance of most symptoms within 4-6 weeks, pictures of "follicular ileitis" persisted for several months.

2314 RADIOGRAPHIC EVALUATION OF COMPLICATIONS AFTER JEJUNOILEAL BYPASS SURGERY. (Eng.)

Moss, A. A.; Goldberg, H. I.; Koehler, R. E. (Univ. California Sch. Medicine, San Francisco, CA 94143). *Am. J. Roentgenol.* 127(5):737-741; 1976.

A retrospective analysis of 89 patients who underwent jejunoileal bypass surgery for morbid obesity was carried out to determine the number, type, and incidence of complications in which radiographic findings were instrumental in the diagnosis. Thirty-three complications were detected radiographically. These included obstruction (10.1%), cholecystitis and cholelithiasis (5.6%), renal stones (4.5%), peptic ulcers (3.4%), megacolon (6.7%), and jejunal elongation and jejunal and ileal mucosal hypertrophy (6.7%). The most common cause of obstruction was jejunoileal intussusception. Other causes included incarcerated umbilical hernia, volvulus of the jejunum, volvulus and herniation, and misplaced suture. Gallbladder disease occurred only in female patients and was detected 2 weeks to 4 yr after bypass. In the patients with megacolon, the colon was dilated to greater than 7 cm. Ulcerations were not seen, and persistent metabolic or electrolyte abnormalities were not observed. The lack of response to prostaglandin E_1 in the one patient in whom it was administered suggests that some type of autonomic dysfunction is involved in the development of megacolon in these patients.

2315 ABSORPTIVE AND DIGESTIVE FUNCTION OF THE JEJUNUM AFTER JEJUNOILEAL BYPASS FOR TREATMENT OF HUMAN OBESITY. (Eng.)

Fogel, M. R.; Ravitch, M. M.; Adibi, S. A. (Montefiore Hosp., Pittsburgh, PA 15213). *Gastroenterology* 71(5):729-733; 1976.

Leucine, glycylleucine, and glucose absorption rates, and rates of maltose hydrolysis, were determined in the jejunum of seven patients before and 2-20 months after jejunoileal bypass for the treatment of obesity. The leucine absorption rate was significantly reduced after the bypass, but the absorption rates of glycylleucine and glucose, as well as the hydrolysis rate of maltose, were unchanged. Light microscopic investigation of the jejunal mucosa, obtained by a p.o. biopsy technique before and 7 months after the bypass operation, revealed no changes in the histological appearance of this tissue. The plasma aminograms of all patients were compared before and at intervals after the bypass operation; all seven exhibited a constant pattern of change that was characterized by significant decreases in the concentrations of serine and glycine and by significant decreases in the concentrations of valine, isoleucine, leucine, tyrosine, and phenylalanine. This pattern of change, which is characteristic of protein depletion, persisted during the entire period of observation. Two of these seven patients developed laboratory evidence of hepatic dysfunction (transaminase elevations between 90 and 202 IU). It is concluded that protein depletion is common to all patients with jejunoileal bypass, with or without hepatic dysfunction, and that protein depletion results in a sustained reduction in free amino acid absorption in the jejunum.

2316 HEPATIC EFFECTS OF JEJUNOILEAL BYPASS FOR MORBID OBESITY. (Eng.)

Holzbach, R. T. (Cleveland Clinic Foundation, Cleveland, OH 44106). *Am. J. Clin. Nutr.* 30(1):43-52; 1977.

The effects of jejunoileal bypass on the liver are reviewed. The most common hepatic consequence of jejunoileal bypass for morbid obesity is triglyceride accumulation, which usually appears to be maximal during the period of acute weight loss. In some patients, however, because of unknown factors such as the degree of steatosis, its duration, or an as yet undefined unusual patient susceptibility, inflammation and fibrosis occur, culminating in cirrhosis. Certain analogies with alcohol-induced steatosis and its consequences are possible. Given differences between the two states for increased intracellular hepatocyte redox potential and possibly different predominant sources for fatty acid mobilization and production affecting increased intracellular triglyceride synthesis, the remainder of the pathway proposed for the development of cirrhosis from ethanolic liver disease may equally apply to the cirrhosis seen in postbypass patients. This complication, although rare (approximately 3%), has been the subject of recent reports of death or near-death from hepatic failure.

43 IMMUNOFLUORESCENT ANTIBODIES AGAINST GLIADIN: A SCREENING TEST FOR COELIAC SEASE. (Eng.) Burgin-Wolff, A.; Hernandez, R.; st, M.; Signer, E. (Universitats-Kinderklinik, mergasse 8, CH-4058 Basel, Switzerland). *Helv. ediatr. Acta* 31(4/5):375-380; 1976.

immunofluorescence test for gliadin antibodies s evaluated for its usefulness as a screen for liac disease. The presence of specific antibodies either gliadin or cow milk protein in human sera s detected by indirect fluorescence-labeling of arose beads coupled to these antigens. Rabbit ti-human IgM, IgA, IgG, and fluorescein-marked at anti-rabbit Ig antisera were used to selective- label the beads. Twenty-three children with oven celiac disease, 71 children with other malab- rptive disorders, and 20 healthy adults were sted for gliadin and cow milk antibodies by the munofluorescence test, the Ouchterlony test, and mplement fixation. The immunofluorescence test s positive for 19 (83%) patients with celiac sease, 3 (4%) patients with other malabsorptive sorders, and none of the healthy adults. In con- ast, the Ouchterlony test and complement fixation tected gliadin antibodies in only 8 (35%) and 12 (52%) of the patients with celiac disease, resp. Gliadin antibodies were also differentiated by immunoglobulin class in the immunofluorescence test. The rate of disappearance of gliadin antibodies in the blood upon prolonged treatment with a gluten-free diet was irregular, and the absence of gliadin antibodies in 4 of the 23 patients with celiac disease was attributed to insufficient gluten in their diet prior to blood sampling. The test for antibodies to cow milk proteins was positive in 91% of the celiac patients, but could not be used in diagnosis of celiac disease since antibodies were also detected in 49% of the patients with other malabsorption disorders. However, the gliadin antibody test proved to be a very sensitive screening method for celiac disease.

2344 THE ENDOSCOPIC DEMONSTRATION OF COELIAC DISEASE. (Eng.) Stevens, F. M.; McCarthy, C. F. (Regional Hosp., Galway, Ireland). *Endoscopy* 8(4):177-180; 1976.

Endoscopic examination and mucosal biopsy of the duodenal cap were carried out in 11 untreated adult celiac disease patients, in 4 treated adult celiac patients, and in 25 patients without this disease to determine whether the procedure is an acceptable alternative to suction biopsy from the region of the ligament of Treitz for the diagnosis of celiac disease. In the untreated celiac patients, the mucosa had pale or erythematous patches. Blood vessels were obvious in some areas. No petechiae were noted, and the mucosa did not traumatize easily. In these patients and in two treated patients who either did not adhere to the gluten-free diet or had only been on the diet for 4 weeks, villous atrophy similar to that found in the distal duodenum and jejunum was seen in the duodenal cap. Villi were seen in the duodenal caps of all controls and in two treated celiac patients who had adhered to a gluten-free diet for at least 6 weeks. The application of indigo carmine to the mucosal surface made the mucosal contours more obvious. Finger and leaf villi were seen endoscopically in nonceliac patients, which contrasted with the flat mosaic appearance in the untreated celiac patients. In the duodenal cap biopsy specimens of the untreated patients, characteristic changes found in the jejunum in celiac disease were seen (i.e., flattening of columnar epithelium with loss of basal orientation of their nuclei, increased numbers of intraepithelial lymphocytes, a preponderance of plasma cells and lymphocytes in the lamina propria, and severe villous atrophy). The results indicate that the endoscopic appearance of the duodenal cap in celiac disease is similar to that of the more distal areas of the small intestine.

2345 ULTRASTRUCTURAL LOCALIZATION OF IgA GLOBULINS IN NORMAL AND COELIAC INTESTINAL MUCOSA USING IMMUNOENZYMATIC METHODS. (Eng.) Jos, J.; Labbe, F. (INSERM, Hopital des Enfants-Malades, 149 rue de Sevres, 75730 Paris Cedex 15, France). *Biomedicine* 24(6):425-433; 1976.

Peroxidase-labeled antibodies were employed in the electron microscopic localization of IgA in duodenojejunal biopsies from three children with active celiac disease and from four controls. Monospecific antibodies were bound to horseradish peroxidase, and intestinal biopsies were successfully penetrated after being fixed in 4% formaldehyde for 20 hr. The present ultrastructural observations confirmed earlier immunofluorescent findings that the healthy duodenojejunal mucosa contains a large number of IgA plasma cells, particularly in the lamina propria. Previous ultrastructural localization of the immunoglobulins in the perinuclear space and rough endoplasmic reticulum of immunocytes was confirmed; the pattern is similar to that observed in IgG plasma cells. The theory that the immunoglobulins pass through the basement membrane of the epithelium, combine with the secretory component, and enter the epithelial cells before passing through to the lumen was confirmed. However, unlike a previously reported study, IgA was mostly observed on the lower, rather than the upper, part of the lateral cell membranes. Abnormally high densities of IgA plasma cells were observed in the mucosae of children with active celiac disease. Particularly heavy deposits were seen on the basement membrane of epithelial cells and the wall of blood vessels. It is concluded that immunoenzymatic methods are useful
in studying the ultrastructural localization of immu
globulins.

2346 MEGACOLON ASSOCIATED WITH CELIAC SPRUE:
PORT OF FOUR CASES AND REVIEW OF THE LITER
TURE. (Eng.) Kappelman, N. B.; Burrell, M.; Troffler, R. (Johns Hopkins Hosp., Baltimore, MD 21205). *Am. J. Roentgenol.* 128(1):65-68; 1977.

The cases of four patients with megacolon in associa
tion with celiac sprue are reported. The patients
cluded a 55-yr-old man with a 15-yr history of diar-
rhea, a 13-month-old girl, a 21-month-old girl, and
a 6-yr-old girl. The two youngest patients had moto
growth retardation and other symptoms of malabsorp-
tion, and the 6-yr-old girl had a 3- to 4-month his-
tory of progressive vomiting, diarrhea, weight loss,
and abdominal distention. None of the patients had
constipation. Barium enema examination revealed a
dilated redundant colon with normal evacuation in
all patients. Upper gastrointestinal series demon-
strated thickened mucosal folds and only minimal
small bowel dilatation. Small bowel biopsies were
consistent with celiac disease in the three patient
in whom they were performed. All patients responde
to a gluten-free diet. Megacolon in these patients
may be related to increased total bulk delivered to
the colon and/or to an intrinsic colonic abnormalit
of celiac sprue.

2347 TRANSIENT PARAPROTEINAEMIA IN A PATIENT
WITH COELIAC DISEASE. (Eng.) Pena, A. S
Nieuwkoop, J.; Schuit, H. R. E.; Hekkens, W. T. J.
Haex, A. J. C. (State Univ. Hosp., Leyden, Netherlands). *Gut* 17(9):735-739; 1976.

A case is reported of a 43-yr-old man with a grass
pollen allergy and a malabsorption syndrome in whom
a paraproteinemia was found. The grass pollen hype
sensitivity was abolished by desensitization. The
malabsorption syndrome was caused by celiac disease
the jejunal mucosa appeared flat, while the ileal
mucosa was almost normal. Clinical recovery and mo
phological improvement resulted when the patient wa
placed on a gluten-free diet. A short period of gl
ten reintroduction caused deterioration of the jeju
nal histology. The monoclonal IgG-λ dminished and
disappeared in the course of 3 yr. Although it was
not possible to demonstrate that this paraprotein h
antigliadin activity, it is suggested that the
constant stimulation of the gut reticuloendothelial
system by gluten might have been related to the
appearance of the paraproteinemia.

2348 LACTASE DEFICIENCY: A COMMON GENETIC TRA
OF THE AMERICAN INDIAN. (Eng.) Newcomer
A. D.; Thomas, P. J.; McGill, D. B.; Hofmann, A. F.
(Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Gastroenterology* 72(2):234-237; 1977.

To determine the prevalence and age of onset of lac
tase deficiency in American Indians, intestinal lac
tase activity was assessed indirectly in 156 India

by measuring breath hydrogen after a p.o. lactose load. Lactase deficiency was present in 66% of the subjects and correlated highly with the percentage of Indian blood. Lactase deficiency was present by the age of 5 yr and was unrelated to sex. Most lactase-deficient subjects (81%), but only a minority (23%) of lactase-sufficient subjects, developed symptoms after the p.o. lactose load, and among lactase-deficient subjects, symptoms occurred more frequently in adults than in children (p=0.05). By history, 53% of lactase-deficient adults, but only 10% of lactase-deficient children under 18 yr of age, were aware of milk intolerance. Despite these differences, milk consumption was only slightly less (19 g) in the lactase-deficient subjects than in those with normal lactase activity (25 g, p<0.05). The results indicate that lactase deficiency is a common autosomal genetic trait in the American Indian that becomes manifest in early childhood. Tolerance to dietary lactose appears to decline in the American Indian as he reaches adulthood, but in this population, the decline in tolerance had only minor influence on lactose intake.

2369 INCIDENCE OF DIARRHEA AND COLITIS ASSOCIATED WITH CLINDAMYCIN THERAPY. (Eng.) Neu, H. C.; Prince, A.; Neu, C. O.; Garvey, G. J. (Columbia Univ. Coll. Physicians and Surgeons, 630 West 168th St., New York, NY 10032). *J. Infect. Dis.* 135(Suppl.):S120-S125; 1977.

Side-effects associated with the oral and parenteral use of the antimicrobial agent, clindamycin, were investigated in a retrospective and prospective study of 200 patients who received the drug for a 15-month period. The age of the patients ranged from 3 to 95 months. Gastrointestinal symptoms were observed in 43 (21.5%) of the patients, while 27 (13.5%) had diarrhea, and 5 (2.5%) developed proven colitis. The mean ages of patients with and without gastrointestinal symptoms were 49.6 and 48.7 yr, resp. The mean age for patients with diarrhea was 61 yr. Diarrhea was observed in 33% of the patients older than 71 yr, and in only 11% of the patients 30 yr old or younger, indicating a much larger incidence of this particular side-effect with increasing age. A higher incidence of gastrointestinal symptoms and diarrhea occurred when clindamycin was administered parenterally rather than orally. Females had a higher incidence of gastrointestinal symptoms and diarrhea than did males. Use of clindamycin in the presence of another antibiotic did not significantly increase the incidence of gastrointestinal symptoms and diarrhea. The frequency of clindamycin-associated diarrhea, according to the condition being treated, was: 20% for ear, nose, and throat infections; 15% for gastrointestinal disease; 14% for respiratory infection; and 11% for gynecologic disease. There was no diarrhea with orthopedic and cutaneous infections. Finally, most gastrointestinal effects were eventually alleviated by discontinuing clindamycin treatment. It was concluded that the incidence of side-effects associated with clindamycin is not as great as previously reported. The drug can b used with caution as a treatment for anaerobic infe tions in adults and children.

2370 ANGIODYSPLASIA OF THE COLON: DIAGNOSIS AN TREATMENT. (Eng.) Wolff, W. I.; Grossman M. B.; Shinya, H. (Beth Israel Medical Center, 10 Nathan D. Perlman Place, New York, NY 10003). *Gastroenterology* 72(2):329-333; 1977.

The cases of three patients who had long-standing gastrointestinal bleeding secondary to intestinal vascular malformations are reported. The patients were elderly men (67-75 yr). The malformations wer all submucosal, and were not detected on barium ene examination. The first patient had a 1-yr history of recurrent rectal bleeding; at the time of the initial hemorrhage, an emergency hemigastrectomy had been performed. Colonoscopy revealed a lesion approximately 3 cm distal to the ileocecal valve, and a right hemicolectomy was performed. The histologic examination suggested hereditary hemorrhagi telangiectasia. The second patient had a 3-month history of intermittent blood in the stools. Colon scopy was performed to the cecum, where multiple areas of telangiectasia were seen. There was no active bleeding at that time. Angiography did not demonstrate this lesion or the presence of other vascular malformations. Right hemicolectomy was carried out, and the histopathological diagnosis was angiodysplasia of the bowel. The third patient had recurrent undiagnosed rectal bleeding (fresh or dark blood) for 6 yr. Physical examination reveale a telangiectatic lesion on the inner side of the lower lip. Angiography of the entire intestine via the celiac axis and inferior mesenteric arteries disclosed a possible arteriovenous malformation in

ne cecum, which was confirmed by colonoscopy. There
as evidence of slow, active bleeding. A right
emicolectomy was performed; in all patients, this
rocedure resulted in the resolution of symptoms.
ndoscopy is a simple method of detecting intestinal
ascular malformations.

371 VASCULAR DYSPLASIA OF THE CECUM AS A REPEATED SOURCE OF HEMORRHAGE: ROLE OF
OLONOSCOPY IN DIAGNOSIS. (Eng.) Thanik, K. D.;
hey, W. Y.; Abbott, J. (Genessee Hosp., 224 Alex-
nder St., Rochester, NY 14607). *Gastrointest.*
ndosc. 23(3):167-169; 1977.

he case of a 56-yr-old man in whom vascular dys-
lasia of the cecum was the source of recurrent
astrointestinal bleeding is presented. The patient
ad a 4-yr history of painless bloody diarrhea and
eakness. During this period, he underwent barium
xaminations, laparotomy, transverse colostomy, and
ngiographic studies, none of which revealed the site
f bleeding. Three colonoscopic examinations through
ne colostomy, one of which was carried out during
nonbleeding period, were unremarkable. A fourth
olonoscopic examination, performed during a bleeding
eriod, revealed a small erosion in the cecum. The
atient is asymptomatic 22 months after an ileo-
scending colectomy was performed. Histologically,
ne lesion appeared as a localized collection of
nin-walled, dilated, venous channels, which were
ined with endothelium and were confined to the mu-
osa and submucosa. The judicious use of fiberoptic
olonoscopy is helpful in determining a source of
emorrhage in the large intestine.

372 BENIGN ULCERATION OF THE CECUM. (Eng.)
Brodey, P. A.; Hill, R. P.; Baron, S. (Mt.
ion Hosp. and Medical Center, P.O. Box 7921, San
rancisco, CA 94120). *Radiology* 122(2):323-327;
977.

hree cases of benign ulceration of the cecum are
resented. Two patients, a 50-yr-old man and a 30-
r-old woman, both heroin users, presented with ab-
ominal pain; emesis and diarrhea were present in
ne first patient, but no hemorrhage was present.
ne third patient, a 44-yr-old man, presented with
elena. In the first two patients, barium enema
xamination revealed a markedly abnormal cecum,
ondistensible in one case and at least partially
istensible in the other. The distorted appearance
as caused by inflammatory reaction, making an
ntrinsic abnormality more likely than secondary
nvolvement due to an extrinsic process. Both
atients were treated surgically. In the third
atient, a selective superior mesenteric artery
njection demonstrated an extravasation of contrast
edium in the region of the cecum. The bleeding
as controlled with vasopressin, although the cecum
nd terminal ileum were resected 7 days later. The
erminal ileum in all patients was normal. Acute
lceration of the cecum should be included in the
adiological differential diagnosis of an abnormal
ecum either shown on barium enema examination or
hen bleeding is demonstrated angiographically in the
ecal region.

LARGE INTESTINE

Ulcerative Colitis

06 VIRAL DNA IN INFLAMMATORY BOWEL DISEASE: CMV-BEARING CELLS AS A TARGET FOR IMMUNE-
EDIATED ENTEROCYTOLYSIS. (Eng.) Roche, J. K.;
uang, E. S. (Duke Univ. Medical Center, Durham,
: 27710). *Gastroenterology* 72(2):228-233; 1977.

nsitive biochemical techniques were used in an
tempt to detect mature cytomegalovirus (CMV) in
seased tissue of patients with inflammatory bowel
sease. Membrane complementary RNA-DNA hybrid-
ation showed that CMV DNA was not detectable
three cases of Crohn's disease, nor was it pre-
nt in three of four cases of ulcerative colitis
amined. Five tissue specimens taken 5 cm from
colonic tumor were also negative. An *in situ*
bridization study of diseased tissue, including
ecimens from six patients with inflammatory bowel
sease and those patients already mentioned, showed
few grains distributed over cells superficial to
e muscularis mucosa; this was not regarded as signi-
icantly different from that in controls. The asso-
iation of CMV with Crohn's disease (0 positives in
patients by either test) is not supported by
is study; the association with ulcerative colitis
positive in 9 patients by either test) requires
rther study before a definitive conclusion can be
de.

07 THE GLYCOCALYX OF THE EPITHELIAL CELLS OF THE COLON, OBSERVED IN NORMAL AND ULCEROUS
LITIC CONDITIONS. (Eng.) Ceralli, F.; Familiari,
; Marinozzi, G.; Muccioli-Casadei, D. (Istituto di
atomia Umana Normale dell'Universita, Viale Regina
ena 289, Rome, Italy). *Experientia* 32(12):1542-
44; 1976.

The polysaccharide coat in the epithelium of normal colon and in that affected by ulcerative colitis was studied ultrastructurally. The surface of normal epithelial cells was covered by a glycoprotein that apparently cemented the adjacent cells. This coat was thinner in ulcerative colitis, and fibrillar bridges of polysaccharide-like material were stretched from one membrane to another. In normal cells, the glycocalyx appeared as a continuous coat on the surfaces of the microvilli, which were regular in number and disposition. In colitis, the glycocalyx formed a loose, irregular net, which left the microvilli exposed; the microvilli were less numerous and were irregularly distributed. These alterations may be related to the action of lymphocytes sensitized in the pathogenic process.

PANCREAS

10 ABERRANT PANCREAS AND LEIOMYOMA OF THE STOMACH: INDISTINGUISHABLE RADIOLOGIC
D ENDOSCOPIC FEATURES. (Eng.) Perrillo, R. P.;
ckerman, G. R.; Shatz, B. A. (Washington Univ.
h. Medicine, 660 S. Euclid Ave., Saint Louis, MO
110). *Gastrointest. Endosc.* 23(3):162-163; 1977.

Two case reports that demonstrate that aberrant pancreas and leiomyoma of the stomach may produce indistinguishable radiologic and endoscopic features are presented. The first patient, a 54-yr-old asymptomatic woman, was hospitalized after upper gastrointestinal radiography revealed a 2 cm^2 submucosal gastric mass immediately proximal to the angulus on the lesser curvature. Endoscopic examination revealed that the surface was smooth and without central umbilication. Gastric leiomyoma was diagnosed, but wedge biopsy revealed encapsulated aberrant pancreatic tissue. In the second patient, a 30-yr-old woman with postprandial nausea, radiography revealed a small filling defect with a central depression on the greater curvature of the antrum; endoscopic examination revealed a submucosal sessile mass with central umbilication and intact overlying mucosa. This was thought to be aberrant pancreatic tissue, and the mass was snared, electrocoagulated, and retrieved. Histological examination revealed a well-differentiated, nonencapsulated, smooth muscle tumor arising from the muscularis mucosae, with smooth muscle cells interdigitating between the gastric glands. The first case illustrates that caution must be used in the diagnosis of leiomyoma on the basis of "typical" smooth surface and location in the body of the stomach. The second case demonstrates that the feature of a central umbilication occurs also in gastric leiomyoma.

2411 ISOAMYLASES IN PANCREATIC CARCINOMA AND CHRONIC RELAPSING PANCREATITIS.

(Eng.) Skude, G.; Ihse, I. (Malmo General Hosp., S-214 01 Malmo, Sweden). *Scand. J. Gastroenterol.* 12(1): 53-57; 1977.

Pancreatic isoamylase activity in the serum and in duodenal aspirates from 12 control subjects, 7 patients with pancreatic carcinoma, and 13 patients with chronic relapsing pancreatitis was studied. A recently developed electrophoretic technique for the separation of salivary and pancreatic isoamylases was used. Total serum amylase appeared normal in most patients, despite subnormal pancreatic amylase activity in three patients with cancer and in seven patients with pancreatitis. Total duodenal amylase activity was normal in all but one patient who exhibited below normal levels of pancreatic isoamylase activities. Patients with below normal pancreatic serum amylase activities also had very low levels of pancreatic duodenal isoamylases. However, half of the patients with low enzyme levels in the duodenum showed serum activity above the lower normal limit. This may have been due to some remaining ability of the pancreas to secrete or to enzymes flowing into the capillary system from blocked secretory ductuli. Two patients who had normal serum amylase activities showed abnormal isoamylase patterns in both the serum and duodenal aspirates. Serum amylase determination may be an effective test in screening for conditions affecting pancreatic exocrine functions.

2412 ISOLATION OF A GLYCOPROTEIN ANTIGEN FROM ASCITES FLUID OF PANCREATIC CARCINOMA.

(Eng.) Chu, T. M.; Holyoke, E. D.; Douglass, H. O. (Roswell Park Memorial Inst., Buffalo, NY 14263). *Cancer Res.* 37(5):1525-1529; 1977.

A glycoprotein antigen from the ascites fluid of pancreatic carcinoma was isolated with the use of perchloric acid extraction and chromatographies on Sepharose 4B, DEAE-Sephadex, and DE52, followed by Sephadex G-200. This antigen was compared biochemically and immunologically with the carcinoembryonic antigen (CEA). The purified glycoprotein was found to be homogeneous by sodium dodecyl sulfate polyacrylamide gel electrophoresis. A molecular weight of 185,000 daltons was determined by gel filtration. The molecule contained 55% protein and 45% carbohydrate. Both the amino acid and carbohydrate compositions were different from those of CEA. This glycoprotein antigen of pancreatic cancer cross-reacted with CEA; however, the antiserum prepared from this antigen did not react with CEA. The biological significance of this glycoprotein in pancreatic cancer has not yet been determined.

2413 MECONIUM ILEUS EQUIVALENT IN ADULTS WITH CYSTIC FIBROSIS OF PANCREAS: A REPORT OF SIX CASES.

(Eng.) Hodson, M. E.; Mearns, M. B.; Batten, J. C. (Brompton Hosp., London SW3 6HP, England). *Br. Med. J.* 2(6030): 790-791; 1976.

Eleven episodes of meconium ileus equivalent (i.e., intestinal obstruction in cystic fibrosis patients with the obstruction occurring outside the neonatal period) in six patients are reported, and the case reports are presented. The patients ranged in age from 21 to 26 yr. The presenting symptoms included colicky abdominal pain, vomiting, and constipation. Fecal impaction was present in the terminal ileum in all patients and was detected by abdominal radiographs, which showed fluid levels in the small bowel; in some cases the obstruction was detected as a palpable mass in the right iliac fossa. Three patients were initially treated surgically; one died, and the other two developed serious postoperative chest infections. Six episodes were successfully treated medically with acetylcysteine, p.o., and by enema, nasogastric suction, and i.v. fluids. Four patients have been successfully maintained on p.o. acetylcysteamine.

2414 EFFECT OF SECRETIN SNIFF ON EXOCRINE PANCREATIC FUNCTION IN CYSTIC FIBROSIS.

(Ger.) Hottinger, S.; Biland, F.; Bender, S.; Hadorn, B. (Med. Univ.-Kinderklinik und Poliklinik, Inselspital Bern, Freiburgstrasse 23, 3010 Bern, Switzerland). *Praxis* 64(38):1209-1213; 1975.

A report on the long-term administration of secretin in nose drop form to achieve improved fat and nitrogen absorption coefficients, and therefore functiona normalization of the pancreas, in cystic fibrosis is presented. Five children with cystic fibrosis were involved in the study. The patients received porcin secretin and cholecystokinin in physiological NaCl solution for nasal infiltration. Preparations containing well-known fat and nitrogen proportions were fed to the children; quantities not consumed were deducted from the calculated food intake. Pancreozymin-secretin tests and enzyme determinatio were performed to check exocrine pancreatic functio Two 5-day balance periods to establish fat and nitro en absorption coefficients were used, the first as without the administration of secretin, and in ne second, secretin-containing dose drops (187-375 ; approximately 45 U/kg/day) were administered efore meals. An additional check on pancreatic unction in the pancreozymin test consisted of comaring bicarbonate output with chymotrypsin output. ecretin improved the fat digestion in patients with ormal or partially disturbed pancreatic function, n whom the steatorrhea had not exceeded 6 mg/24 hr. n normal control patients, a correlation between oth values was obvious, while in cystic fibrosis, igh bicarbonate secretion persisted despite partialy normal chymotrypsin values. It was found that ecretin promoted bicarbonate and water secretion f the gland and induced a complete rinse-out of nzymes still formed in the pancreas in adequate uantities, leading to a higher total digestive ffect.

415 INHIBITION OF GASTRIC SECRETION IN TREATMENT OF PANCREATIC INSUFFICIENCY. (Eng.) aunders, J. H. B.; Drummond, S.; Wormsley, K. G. Ninewells Hosp., Dundee DD2 1UB, Scotland). r. *Med. J.* 1(6058):418-419; 1977.

ne effects of metiamide inhibition of gastric seretion on the gastric transit of pancreatic enzymes ere studied in patients with pancreatic achylia fter a standard meal supplemented with pancreatic xtract. The duodenal pancreatic enzyme content as measured during a test meal before and after reatment with metiamide (1 g/day). Gastric transit f the enzymes, with the appearance of near-normal mounts in the duodenal contents, occurred only fter metiamide inhibition of gastric secretion and uffering of residual gastric acid with antacids. ne results indicate that gastric inhibition and eutralization of acid are necessary for the satisactory treatment of patients with pancreatic exorine insufficiency but with normal gastric function.

416 EXOCRINE PANCREATIC INSUFFICIENCY AND PRIMITIVE MALNUTRITION. (Eng.) Descos, L.; uclieu, J.; Minaire, Y. (Inserm U 45, Hopital Edouarderriot, F-69374 Lyon Cedex 2, France). *Digestion* 5(1):90-95; 1977.

ancreatic function during secretin stimulation was bserved before and after dietary therapy in four atients suffering from primitive malnutrition. The atients, 37-59 yr old, presented with weakness, uscular atrophy, anemia, low plasma albumin/globulin atios, and weight losses from 9-29% as a result of 3-2 months of inadequate food intake. A high-proteinalorie diet of more than 45 kcal/kg for 4 weeks was dministered. Before dietary therapy, pancreatic flow as below the lower normal limit in only two of our patients (14-49 ml/min), while the maxial bicarbonate concentrations (58-74 mM) and ipase activities (500-860 IU) were always beow the normal limits. Three patients had lowered rypsin activity (16-32 IU), and one patient ad lowered chymotrypsin activity, but all paients had normal amylase activity. Four weeks of therapy greatly improved the maximal bicarbonate concentration (76-110 mM) and lipase activity (760-1,563 IU), but had less and more irregular effects upon pancreatic flow, trypsin, and chymotrypsin activities. The patients also had partial weight recoveries of 0-16%. Pancreatic function appears to recover more quickly from primitive malnutrition than body weight. Furthermore, the maximal bicarbonate concentration and lipase activity are more sensitive to malnutrition, but also more responsive to renutrition, than are pancreatic flow, trypsin and chymotrypsin activities.

2417 EXOCRINE PANCREATIC INSUFFICIENCY SYNDROME IN CBA/J MICE. I. ULTRASTRUCTURAL STUDY. (Eng.) Eppig, J. J.; Leiter, E. H. (Jackson Lab., Bar Harbor, ME 04609). *Am. J. Pathol.* 86(1): 17-30; 1977.

The pathogenesis of a spontaneously occurring exocrine pancreatic insufficiency (EPI) syndrome was studied by electron microscopy in CBA/J mice. The initial cytologic manifestations of this syndrome were seen as a progressive digestion of the zymogen granules, beginning at the periphery and proceeding toward the granule interior. Granule membrane breakdown, fusion of neighboring granules, and a release of zymogen contents into the cytoplasm were frequently observed in later stages; in some cases, the entire granule contents appeared to be digested before membrane breakdown was observed. In either case, pathologic changes were subsequently observed in mitochondria and rough endoplasmic reticulum. Remnants of lysed cells were then engulfed by invading macrophages, and infiltration by fat cells was observed. Secretory ducts and islets of Langerhans showed no pathologic changes, even after total autolysis of the exocrine pancreas. Morphologic evidence showing zymogen granule destabilization, coupled with biochemical evidence, indicate that intracellular autodigestion is the mechanism of exocrine cell death.

2418 EXOCRINE PANCREATIC INSUFFICIENCY SYNDROME IN CBA/J MICE. II. BIOCHEMICAL STUDIES. (Eng.) Leiter, E. H.; Dempsey, E. C.; Eppig, J. J. (Jackson Lab., Bar Harbor, ME 04609). *Am. J. Pathol.* 86(1):31-46; 1977.

Premature activation of proteolytic zymogens (trypsinogen, chymotrypsinogen) as an early step in the pathogenesis of exocrine pancreatic insufficiency (EPI) syndrome was investigated in electrophoresed pancreatic homogenates from CBA/J mice. Polyacrylamide gels containing extracts from control pancreas required prior activation of trypsinogen and chymotrypsinogen to produce activity staining with specific synthetic substrates. Bands of activity staining in gels containing homogenates from mice with EPI syndrome were readily detected without trypsin or enterokinase preincubation. Subcellular fractionation of control and diseased pancreas revealed that the premature intracellular proteolysis was confined to the zymogen granule fraction, which, even in very moderately affected pancreases (10-30% acinar cell autolysis), was very labile *in vitro*. These proteolytic events reflect the biochemical consequences of zymogen granule destabilization that have been observed at the ultrastructural level.

2429 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE EVALUATION OF PANCREATIC DISEASE. (Eng.) Novis, B. H.; Narunsky, L.; Bank, S. (Groote Schuur Hosp., Cape Town, South Africa). *S. Afr. Med. J.* 50(39):1501-1505; 1976.

The endoscopic retrograde cholangiopancreatography (ERCP) findings in 98 patients with unexplained abdominal pain or known pancreatitis with recurrent pain are reported, and the results were compared with those of the standard secretin-cholecystokinin test for pancreatic secretory function (PFT). Patients with jaundice were excluded from the study. The radiological findings on ERCP were graded in 38 patients with pancreatitis. Advanced pancreatitis was found in 20 patients (52.5%), moderate changes in 7 (18.4%), and minimal-change pancreatitis in 6 (15.8% Five patients had normal pancreatograms. In 35 patients investigated for unexplained abdominal pain, changes consistent with pancreatitis were found in 7 pancreatic carcinoma in 5, a duodenal ulcer in 2, gallstones in 1, and a duodenal tumour in 1. ERCP demonstrated a normal pancreas in 19 patients. A co parison of the ERCP findings and those of the standard secretin-cholecystokinin pancreatic function test was made in 52 patients. There was a good agre ment between the two tests in the patients with advanced or moderate pancreatitis, as revealed by ERCP but less agreement in the patients with minimal-chan pancreatitis. A few patients with clinical pancreatitis and abnormal ERCP had normal pancreatic function tests. ERCP increases the diagnostic yield in

ents suspected of having pancreatitis and is the
reliable method of diagnosing pancreatic carcin-
not evident by other nonoperative techniques. ERCP
lso useful in the assessment of the severity of
reatitis and is a necessary investigation before
reatic surgery to confirm or exclude cyst forma-
or the site of duct obstruction.

DIAGNOSTIC CONSIDERATIONS IN ACUTE ALCOHOLIC AND GALLSTONE PANCREATITIS. (Eng.)
yan, D.; Simonovitz, D. (Univ. Chicago Pritzker
Medicine, 950 E. 59th St., Chicago, IL 60637).
J. Surg. 132(3):329-331; 1976.

y-six patients with alcoholic acute pancreatitis
compared with 64 patients with proved gallstone
te) pancreatitis to determine additional para-
rs useful in distinguishing these two diseases
ng the acute period. Pain, duration of symptoms,
degree or frequency of hypocalcemia were not
ful in differentiating the two groups. The gall-
e patients had significantly higher mean serum
ase (1,855 ± 0.30 mg/100 ml) levels than the alco-
c patients (807 ± 105 IU, p<0.001; 52 ± 6, p<0.05,
.). Jaundice occurred in 27% of the gallstone
ents and in only 12% of the alcoholic patients.
results demonstrate that the serum amylase level
dmission is one of the most useful laboratory
s in the differential diagnosis of alcoholic and
stone pancreatitis.

STENOSIS OF THE COLON IN ACUTE PANCREATITIS.
(Eng.) Mair, W. S. J.; McMahon, M. J.;
gher, J. C. (The General Infirmary, Leeds, Eng-
). *Gut* 17(9):692-695; 1976.

case of a 79-yr-old woman with a stricture of
colon associated with acute pancreatitis is
ented. The patient presented with a 3-month
ory of anorexia, colicky upper abdominal pain,
ting, loose stools, and low grade fever. A
was felt in the right hypochondrium below a
able enlarged liver. A barium enema examination
losed the stricture, with mucosal destruction
he cecum and ascending colon. At laparotomy,
ss was found in the upper abdomen involving the
reas, the right side of the transverse mesocolon,
the contiguous greater omentum. A biopsy showed
necrosis only. As there appeared to be no actual
owing of the bowel apart from that produced by
a, biopsy of the mass was the only procedure
ied out. The postoperative progress was unevent-
and the abdominal pain, vomiting, and diarrhea
lved. Because many cases of colonic stenosis
ssociation with acute pancreatitis have been
used with carcinoma, both radiologically and at
rotomy, a conservative approach should be adopted
ially, resection being carried out if follow-up
um examination fails to show resolution of the
osis.

ACUTE PANCREATITIS OCCURRING IN HETEROTOPIC PANCREATIC TISSUE IN THE GALLBLADDER.
.) Qizilbash, A. H. (Henderson General Hosp., 711 Concession St., Hamilton, Ontario L8V 1C3, Canada). *Can. J. Surg.* 19(5):413-414; 1976.

The rare case of a 54-yr-old man with acute pancreatitis occurring in heterotopic pancreatic tissue in the gallbladder is presented. The patient presented with acute upper abdominal pain. A cholecystectomy was performed. The inflamed gallbladder measured 7.0 x 4.0 cm. No calculi were present, and histologic sections showed acute cholecystitis. Within the gallbladder wall was a 0.5-cm nodule of pancreatic tissue containing both acinar and ductal elements, together with small islets of Langerhans. Portions of the pancreatic tissue and the adjacent gallbladder wall showed large irregular areas of fat necrosis and, in parts, faintly basophilic necrotic foci involved the muscular and mucosal layers of the gallbladder and the surrounding perimuscular and serosal tissues. This case is unusual because definite evidence of acute inflammation and fat necrosis was demonstrated in the aberrant pancreatic tissue and the adjacent wall of the gallbladder. The occurrence of fat necrosis suggests that pancreatic lipase was released into the gallbladder wall.

2433 ANEURYSMS SECONDARY TO PANCREATITIS. (Eng.) White, A. F.; Baum, S.; Buranasiri, S. (Georgetown Univ. Hosp., 3800 Reservoir Rd., N.W., Washington, DC 20007). *Am. J. Roentgenol.* 127(3): 373-396; 1976.

The arteriograms of 72 unselected consecutive cases of suspected pancreatitis and of 84 cases of carcinoma of the pancreas were reviewed to study the association of aneurysms secondary to pancreatitis. Pancreatitis was confirmed in 63 of the 72 cases. Among the pancreatitis cases, seven were found to have arterial aneurysms involving branches of the peripancreatic vessels; no aneurysms of these vessels were found among the arteriograms of the carcinoma patients. The patients ranged in age from 30 to 69 yr, and the duration of pancreatitis was 4-12 yr. The aneurysms occurred in the splenic (2 cases), common hepatic (1), transverse pancreatic (3), and celiac axis and splenic (1) arteries and were 0.3-2.4 cm in size. The demonstration of aneurysms of the peripancreatic arteries in pancreatitis is an important differential feature from carcinoma of the pancreas.

LIVER AND BILIARY TRACT

2448 ABNORMAL REGULATION OF PLASMA PYRIDOXAL 5'-PHOSPHATE IN PATIENTS WITH LIVER DISEASE. (Eng.) Mitchell, D.; Wagner, C.; Stone, W. J.; Wilkinson, G. R.; Schenker, S. (Vanderbilt Univ. Sch. Medicine, Nashville, TN). *Gastroenterology* 71(6):1043-1049; 1976.

The effects of liver disease on the regulation of plasma pyridoxal 5'-phosphate (PLP) were studied in six healthy controls, eight patients with alcoholic cirrhosis, six patients with acute hepatitis, and three patients with extrahepatic obstruction. The plasma PLP level was measured before and sequentially after the rapid i.v. administration of 50 mg of pyridoxine. The base line plasma PLP concentration was significantly lower in cirrhotic patients than in normal persons ($p<0.025$), and there was a tendency for it to be reduced in patients with extrahepatic obstruction. After the administration of pyridoxine, there was a significant increase in the plasma PLP level over a 2- to 12-hr period, after which the concentration returned gradually toward the initial value. The area under the concentration/time curve was 2-8 times smaller ($p<0.002$) in the patients with liver disease than in controls. To assess possible mechanisms of this change, 5 mg PLP were adminisred i.v. to the patients, and the pharmacokinetics the disposition were assessed. The initial and eady state volumes of distribution of PLP were mparable in cirrhotics and controls ($p<0.05$), but e clearance of plasma PLP in cirrhotics was much ster (63.0 ± 7.4 versus 31.7 ± 2.7 ml/min, $p<0.004$). milar findings were obtained in the other liver sease subjects. The *in vitro* plasma binding of PLP supracirculatory concentrations was comparable in rrhotics and controls (99.4 versus 99.5%, $p<0.05$). ese studies show that: plasma PLP regulation in tients with liver disease is abnormal and that a gnificant factor in the decrease in plasma PLP ter i.v. pyridoxine administration in these patients pears to be an increase in the total plasma clearce of the coenzyme; it is postulated that this may due to increased degradation of PLP by the dissed liver.

49 METRONIDAZOLE AND HEPATIC ABSCESS: A FALSE-POSITIVE RESPONSE. (Eng.) Kane, G.; Fossieck, B. E., Jr.; Parker, R. H. (Veterans min. Hosp., 50 Irving St. NE, Washington, DC 422). *JAMA* 236(23):2653-2654; 1976.

e case of a patient with a false-positive response metronidazole therapy for amebic hepatic abscess presented. The patient, a 46-yr-old man, esented with fever, weight loss, diarrhea, and termittent abdominal pain. He had been treated r amebic dysentery 31 yr previously, and hepatic scess was diagnosed on the basis of the results ^{99m}Tc sulfur colloid scan and selective celiac giography. He was treated with metronidazole 50 mg t.i.d., p.o.). Within 12 hr, the patient's mperature fell from 40 C to 37.2 C, and for the xt 7 days it remained below 37.8 C. On the sevth day, his temperature rose to 40 C; emetine drochloride caused a reduction in temperature r 3 days. At this time, amebic antibody titers complement fixation and indirect hemagglutination sts were nonreactive. Chloramphenicol therapy s begun in place of emetine and metronidazole. ploratory laparotomy revealed a hepatic abscess, d extensive microscopic examination of the purunt fluid failed to show *Entamoeba histolytica*. am-positive cocci and gram-negative rods were esent. Aerobic cultures were sterile, and aerobic cultures were positive for microaerophilic reptococci. The patient recovered after continued loramphenicol therapy. The authors believe that is case represents a response to metronidazole susceptible anaerobes involved in the etiology of e abscess.

50 HEREDITARY CHOLESTASIS COMBINED WITH PERIPHERAL PULMONARY STENOSIS AND OTHER ANOMIES. (Eng.) Henriksen, N. T.; Langmark, F.; Sornd, S. J.; Fausa, O.; Landaas, S.; Aagenaes, O. lleval sykehus, Oslo, Norway). *Acta Paediatr. and.* 66(1):7-15; 1977.

e cases of six patients with a hereditary form of olestasis that showed a marked resemblance to rteriohepatic dysplasia" are presented. The paents were followed for 12 yr. All patients were smaller than average at birth, and all except one boy showed neonatal cholestasis and hepatomegaly. Itching persisted for many years, especially in two boys, 11 and 12 yr old. High bilirubin levels, enlarged livers, and hyperlipemia were common in infancy, but tended to normalize with age. Steatorrhea was more predominant in infancy and persisted only in one girl, suggesting that the intestinal function of the bile acids was usually not affected. The serum concentrations of alkaline phosphatase increased with age to higher than normal levels, and alanine- and aspartate-aminotransferases were also increased in all but one girl. Bile acids appeared normal, but their serum concentrations were increased in all but one patient. Liver biopsies revealed greatly reduced numbers of bile ducts in the portal areas and obstructions of the bile capillaries, particularly in infancy, with resultant accumulation of bile pigment in the hepatocytes and inflammation of the portal areas. These observations suggest that defective metabolism or transport of bile acids may be responsible for liver dysfunction. Other characteristics of the syndrome are peripheral pulmonary stenosis, atypical faces with deep-set eyes, broad forehead, flat profile, and vertebral anomalies. Growth retardation was observed in several cases and appeared to be related to the degree of liver dysfunction. Family data suggested an autosomal dominant mode of inheritance.

2451 STUDIES IN CHOLESTASIS OF PREGNANCY. VI. FATTY ACID COMPOSITION OF GLYCERO-PHOSPHOLIPIDS BEFORE AND AFTER DELIVERY. (Eng.) Samsioe, G.; Johnson, P.; Gustafson, A. (Sahlgren's Hosp., Goteborg, Sweden). *Acta Obstet. Gynecol. Scand.* 56(1):31-35; 1977.

The disappearance of lipoprotein X (LP-X) was followed in eight women with cholestasis of pregnancy (CP), and the characteristic fatty acid pattern of serum lecithin was studied before and a few days after delivery. Ten women with an uncomplicated pregnancy served as controls. During pregnancy, all patients with CP had LP-X in their serum; LP-X had disappeared by 4-8 days after delivery in all women. In the women with CP, the mean fatty acid composition of lecithin showed the following changes after delivery: palmitic acid, 16:0 ($p<0.05$); linoleic acid, 18:2 ($p<0.01$). Stearic acid (18:0) and oleic acid (18:1) levels were higher after delivery. The concentration of serum lecithin was also lower after delivery ($p<0.01$). In the controls, the lecithin composition after delivery was lower in palmitic acid (16:0) and higher in stearic acid (18:0).

2452 TREATMENT OF HEPATIC COMA WITH HEMOPERFUSION THROUGH POLYACRYLAMIDE HYDROGEL-COATED CHARCOAL. (Eng.) Gelfand, M. C.; Knepshield, J. H.; Cohan, S.; Ramirez, B.; Schreiner, G. E. (Georgetown Univ. Hosp., 3800 Reservoir Rd. NW, Washington, DC 20007). *Kidney Int.* 10(Suppl. 7): S239-S243; 1976.

The case of a patient with severe hepatic coma who was treated with hemoperfusion through polyacrylamide hydrogel-coated charcoal is presented. The patient, a 34-yr-old man with an 18-yr history of alcohol abuse, was admitted in grade IV coma with a serum bilirubin level of 19.2 mg/100 ml, and SGOT level of 159 U, abnormal clotting indices, guaic-positive stools, and pyrexia. He responded minimally to pain, the pupils responded sluggishly to light, and Babinski reflexes and Doll's eye movements were present. There was no evidence of ascites. The length of the liver by percussion was less than 5 cm in the midclavicular line. He responded minimally to bowel sterilization and treatment with thiamine, multivitamins, phytonadione, potassium, and 4 U of plasma. After approximately 2 hr of hemoperfusion, the patient became responsive to painful stimuli. The pupils became more dilated and reacted promptly to light. Doll's eye movements were no longer present. Within 2 hr of termination of the 4-hr perfusion, the patient returned to grade IV coma. Transfusion with fresh frozen plasma and platelet packs improved the clotting indices. Approximately 24 hr after a second 4-hr perfusion, the patient regained full consciousness. He remained conscious for the next 7 days, at which time his condition was complicated by massive gastrointestinal bleeding, renal failure, and adult respiratory distress syndrome. He again became comatose, but regained full consciousness by a third hemoperfusion. The clotting indices continued to drop, however, and the patient died from uncontrolled upper gastrointestinal tract bleeding complicated by refractory hypotension and oliguria. Serum calcium dropped during hemoperfusion, but were easily restored. Hypotension occurred at the initiation of hemoperfusion, but was reversible with volume replacement. The most serious complication of this procedure was significant decreases in platelet counts, probably due to damage to platelets passing over the coated charcoal. Hemoperfusion may be valuable in the treatment of acute or chronic hepatic failure.

2453 TEMPORARY LIVER TRANSPLANTATION IN ACUTE LIVER FAILURE.

(Eng.) Diaz, A.; Ricco, J. B.; Franco, D.; Gigou, M.; Szekely, A. M.; Bismuth, H. (No affiliation given). *Arch. Surg.* 112(1): 74-78; 1977.

The use of temporary liver transplantation for supporting life during acute liver failure was investigated in mongrel dogs. Acute hepatic failure was produced in 15 dogs by temporary suppression of the entire hepatic blood inflow for 60 min. Nine dogs received an intrathoracic hepatic homograft concurrently. The mean survival time for dogs not receiving transplants was 21 hr (range, 10-28 hr) from beginning of ischemia. The mean survival time for dogs receiving transplants was 7 days (range, 32 hr to 25 days) after the beginning of ischemia. Thus, there was a significant ($p<0.001$) difference between the mean survivals of transplanted and nontransplanted dogs. In dogs undergoing intrathoracic hepatic transplantation, the levels of SGPT and fibrinogen and the prothrombin time returned to normal or near normal within 5 days and were approximately 400 mU/ml, 3.5 g/l, and 15 sec, resp., at that time. In four animals receiving transplants, the graft was removed on the 5th postoperative day, and two of those survived for 10 and 25 days following graft removal and died from unrelated causes (pneumonitis and wound dehiscence). These results demonstrate that a temporary heterotopic liver transplant is able to support life during the acute and normally lethal phase of massive liver necrosis in dogs.

2454 PROGNOSTIC VALUE OF SERUM ALPHA-FETOPROTEIN IN FULMINANT HEPATIC FAILURE INCLUDING PATIENTS TREATED BY CHARCOAL HAEMOPERFUSION.

(Eng.) Murray-Lyon, I. M.; Orr, A. H.; Gazzard, B.; Kohn, J.; Williams, R. (Charing Cross Hosp., London W6, England). *Gut* 17(8):576-580; 1976.

Serum α-fetoprotein (AFP) levels were measured sequentially by a radioimmunoassay method in 64 patients with fulminant hepatic failure to determine the prognostic value of AFP. In 15 of the 64 patients (23%), AFP levels were raised, but in only two did they exceed 500 ng/ml. Of the 23 survivors, 11 (48%) had raised AFP levels, compared with 4 of the 41 (9.8%) fatal cases ($p<0.005$). This rise in AFP levels was found early after the development of grade IV coma and constitutes an encouraging prognostic sign at a time when the liver function tests and EEG are unhelpful. A radioimmunoassay must be used if these small, but significant, rises in plasma concentration are to be detected. Twelve patients survived without showing a rise in plasma AFP at any time during the illness. The four fatal patients, who had raised AFP levels, all had serious complications of fulminant hepatic failure. Charcoal hemoperfusion did not increase the survival of six AFP-negative patients in whom this procedure was carried out.

2455 HEPATIC LESIONS OF CENTRAL PERICELLULAR FIBROSIS IN MORBID OBESITY, AND AFTER JEJUNOILEAL BYPASS.

(Eng.) Marubbio, A. T., Jr.; Buchwald, H.; Schwartz, M. Z.; Varco, R. (Hennepin County Medical Center, Fifth St. and Portland Ave. South, Minneapolis, MN 55415). *Am. J. Clin. Pathol.* 66(4):684-691; 1976.

Histologic findings in liver biopsy specimens obtained from 88 patients before and 1 and 2 yr after end-to-end jejunoileal bypass were compared. In addition to the expected fatty changes, mild changes of centrilobular, pericellular fibrosis were present in the initial biopsies in 8.6%; 1 yr later, these changes were apparent in 46%. Portal-central bridging developed in 6.8% of the patients; early micronodular cirrhosis developed in 3.4% of these patients, all of whom had central pericellular fibrosis. Electron microscopy of prebypass liver biopsies from eight additional patients showed collagen and electron-dense material resembling basement membranes within the spaces of Disse in seven, although only four had light microscopic evidence of minimal central pericellular fibrosis. The existence of these light and electron microscopic changes before jejunoileal bypass suggests that there is a lesion in morbid obesity that may be exacerbated during the first year after operation.

2456 BIOPSY STUDY OF HEPATOCARCINOMAS IN NIGERIAN IGBOS.

(Eng.) Onuigbo, W. J. B. (General Hosp., P.M.B. 1030, Enugu, Nigeria). *Acta Hepatogastroenterol.* 24(1):24-26; 1977.

The clinical factors, histologic appearance, sex distribution, and age distribution of 55 cases of hepatocarcinoma among Nigerian Igbos were studied. The male:female ratio was 2.9:1, and the average age peak was 20-49 yr. Symptoms included abdominal swelling (41 cases), abdominal pain (25), weight loss (16), and jaundice (10). The liver was palpable in almost all patients. Two patients presented acutely with hemoperitoneum due to rupture of a necrotic tumor nodule. Cirrhosis was found in 60% of 20 biopsy specimens. The age peak for hepatocarcinoma among the Igbos is younger than that reported in the U.S., Argentina, and Great Britain. The large proportion of patients presenting with an abdominal mass is also noteworthy. In addition, the incidence of hemoperitoneum is higher in Africans.

2457 SOLITARY HEPATIC HEMANGIOMA IN A NEWBORN INFANT COMPLICATED BY CARDIAC FAILURE, CONSUMPTION COAGULOPATHY, MICROANGIOPATHIC HEMOLYTIC ANEMIA, AND OBSTRUCTIVE JAUNDICE. CASE REPORT AND REVIEW OF THE LITERATURE.

(Eng.) Linderkamp, O.; Hopner, F.; Klose, H.; Riegel, K.; Hecker, W. C. (Universitats-Kinderklinik, Lindwurmstr. 4, D-8000 Munchen, W. Germany). *Eur. J. Pediatr.* 124(1):23-29; 1976.

The case of a newborn infant with a large hepatic hemangioma, congestive heart failure, consumption coagulopathy, microangiopathic hemolytic anemia, and obstructive jaundice is presented. The patient was mildly heparinized (250 U/kg/day) and underwent successful resection of the tumor without lobectomy at the age of 3 days. Blood volume increased from 93.9 ml/kg at the age of 5 hr to 124.2 ml/kg prior to surgery. RBC mass simultaneously decreased from 53.8 to 39.4 ml/kg. The increase of blood volume is explained by congestive heart failure, the decrease of RBC mass is explained by intravascular coagulation within the tumor, resulting in formation of thrombi and microangiopathic hemolytic anemia. A review of the literature on infants with symptoms caused by an intrahepatic hemangioma during the first month of life confirms that surgical intervention is the treatment of choice for infants with giant solitary liver hemangioma.

2458 HEMANGIOENDOTHELIOMATOSIS OF THE LIVER: A 12-YEAR FOLLOW-UP.

(Eng.) Chowdhury, A. R.; Black, M.; Lorber, S. H.; Chey, W. Y. (St. Joseph Hosp., 12th and Walnut St., Reading, PA 19603). *Gastroenterology* 72(1):157-160; 1977.

The case of a 43-yr-old woman with hepatic hemangioendothelioma associated with hepatomegaly and ascites who has been followed for over 12 yr is presented. The patient presented with a 5-month history of increasing abdominal girth and occasional nausea. She consumed approximately 1 quart of whiskey daily and had been exposed to the vapors of organic solvents, including carbon tetrachloride, for 20 yr. The diagnosis of hemangioendotheliomatosis of the liver with considerable fibrosis was made by a wedge biopsy. During the past decade, attempts to discontinue diuretic therapy have resulted in a return of ascites and marked oliguria. On a maintenance diet of 6 g of sodium and omission of diuretics for 2 weeks, plasma renin activity was 1,668 ng/100 ml, and urinary aldosterone excretion was 24 μg/day. Portal hypertension together with secondary aldosteronism were presumably responsible for the formation of ascitic fluid, but the pathophysiological mechanism remains obscure. The patient has remained well on a salt-restricted diet, furosemide, and spironolactone. The relatively benign history of this patient, together with the static liver size, suggest that her hepatic lesions have not grown significantly over the past 12 yr.

2459 HEMOBILIA FOLLOWING NEEDLE BIOPSY OF THE LIVER.

(Eng.) Seltzer, R. A.; Rossiter, S. B.; Cooperman, L. R.; Liebowitz, D. (Sequoia Hosp., Redwood City, CA 94062). *Am. J. Roentgenol.* 127(6):1035-1036; 1976.

An angiographically documented case of hemobilia following liver biopsy in which the bleeding resolved spontaneously is presented. Four days after liver biopsy (which showed chronic viral hepatitis), the patient, a 24-yr-old man, experienced sudden, right upper quadrant and epigastric pain, followed by melena. Four units of blood were required over the next 5 days to maintain the blood hemoglobin. The bilirubin was 8.0 mg/100 ml at the onset of pain, but decreased to 2.7 mg/100 ml when the bleeding subsided. Twelve days after the biopsy, there was an identical episode of epigastric pain, hematemesis, and melena, with an elevation in serum bilirubin and drop in hemoglobin. Twenty-one days after the biopsy, celiac arteriography showed extravasation from a branch of the right hepatic artery into a branch of the right hepatic duct. A third mild episode of hemobilia 3 weeks later subsided with bed rest, and no further bleeding has occurred in the ensuing 6 months. Although uncommon, hemobilia should be considered as a cause of gastrointestinal hemorrhage in a patient who has had a recent liver biopsy.

2460 FOCAL NODULAR LIVER HYPERPLASIA.

(Por.) Pereira-Lima, L.; Miguel, P. R.; Nestrovski, M.; Geyer, G. (Dep. de Cir. da Pont. Univ. Catol. do Rio Grande do Sul, Rio Grande, Brazil). *Rev. Assoc. Med. Bras.* 21(8):237-238; 1975.

A differential diagnosis study is presented based on histopathological findings in two cases of benign tumors of the liver discovered during surgery for duodenal ulcer. In a 39-yr-old woman, laparotomy revealed three yellowish nodular masses in the right lobe of the liver, having a multilobular aspect, a firm consistency, and a superficial location. Following resection of the tumor, the patient experienced recurrent abscesses and septicemia. She was operated three more times then released in good condition 115 days after surgery. One month later, a hepatic scintiscan with ^{113}In revealed a normal aspect of the liver. A 47-yr-old woman subjected to vagotomy and gastroenteroanastomosis had a nodular, cuneiform grayish mass located in the right lobe of the liver. The histological examination of paraffin embedded bioptic specimens determined the diagnosis of focal nodular hyperplasia of the liver (FNHL) in both patients. In stressing the pathogenetic difference between FNHL and true adenomas, at macroscopic examination, FNHL shows one or more areas of fibrosis of stellate shape, which are not found in adenomas. At microscopy the adenoma shows mostly undifferentiated cells without a trace of biliary ducts or portal spaces, while FNHL shows cellular aspects similar to those of the normal liver. It is suggested that the term "FNHL" is preferred to that of hamartoma,, since it better indicates the evolutionary, rather than the congenital, nature of the tumor.

2461 THE NEPHROGENIC HEPATIC DYSFUNCTION SYNDROME. A REVIEW. (Eng.) Strickland, R. C.; Schenker, S. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37203). *Am. J. Dig. Dis.* 22(1):49-55; 1977.

The literature on the nephrogenic hepatic syndrome (NHDS) is reviewed. Patients with renal cell carcinoma occasionally develop hepatomegaly and abnormal liver function tests in the absence of hepatic metastases. This condition is reversible with nephrectomy. Since its discovery in 1961, 29 fully documented cases of this syndrome have been published.
Based on these cases, the syndrome is usually characterized by hepatomegaly, fever, anemia, weight loss, high levels of alkaline phosphatase, prolonged prothrombin time, and abnormal BSP retention. No consistent patterns of histology appear in either renal cell carcinomas or livers associated with the syndrome. Several theories exist as to the etiology of some of the common symptoms. Elevated alkaline phosphatase may be caused by the production of a variant, Regan isoenzyme, by the carcinoma. Regan isoenzyme has been associated with certain other neoplastic tissues, but only two patients with NHDS have been tested, and its presence was detected in only one of these. It has also been suggested that fever may be the major cause of abnormal BSP retention, since this symptom can be induced by pyrexia caused by two very different agents, endotoxin and etiocholanolone. An unsupported, but possible, explanation for NHDS was that the syndrome might be caused by liver metastases that regressed after the primary carcinoma was removed and were, therefore, not detected. Another, so far unsupported, possibility is that the carcinoma may produce a "toxic hormone," which causes liver dysfunction. A more complete understanding of this syndrome will make possible more accurate diagnoses of patients with unexplained liver dysfunctions.

2462 TOXIC ENCEPHALOPATHY AND FATTY ACCUMULATIONS IN THE VISCERA (REYE'S SYNDROME). (Spa.) Cordero, J.; Olivos, P.; Zacarias, J.; Latorre, J. J. (Hospital Luis Calvo MacKenna, Chile). *Rev. Chil. Pediatr.* 45(6):483-490; 1975.

Experience with eight cases of Reye's syndrome with marked prodromal symptomatology (vomiting, fever, convulsions) is reviewed. Physical development was normal, except in one undernourished patient, 48 months old. Fevers and fluctuating pulses with respiratory disorders also occurred. Abdominal symptomatology of hepatomegaly appeared more frequently (7 cases) than did hematemesis (4) and melena (2). Nonsystematized neurological symptoms were convulsions (5), hypotensive coma, hypertension, and decerebration (3 cases); there were six deaths within 13-72 hr. Hematological and serological examinations revealed low prothrombin, leukocytosis, and hyperglutaminemia, indicating hepatic insufficiency and uremia. Pathological anatomy was nonspecific; cerebral edema with congestion and extravascularization, fatty liver, infiltrated renal tubules, and bronchopneumonia were seen. Convulsions called for pheonobarbital sodium (10 mg/kg, i.m.) or diazepam (0.5 mg/kg, i.m.). Neomycin and exchange blood transfusion were given for hepatic insufficiency with increased glutamic-pyruvic transaminase. Glucose solutions were used in i.v. hydration. The two survivors had altered electroencephalograms after 100 days with subsequent normalization of hepatic structures.

2463 HEPATIC DYSFUNCTION IN ASSOCIATION WITH PANCREATIC INSUFFICIENCY AND CYCLICAL NEUTROPENIA: SHWACHMAN-DIAMOND SYNDROME. (Eng.) Brueton, M. J.; Mavromichalis, J.; Goodchild, M. C.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, Francis Rd., Birmingham B16 8ET, England). *Arch. Dis. Child.* 52(1):76-78; 1977.

The results of investigations on four children with the syndrome of pancreatic achylia and cyclical neutr penia (Shwachman-Diamond syndrome) are presented, together with the complete case history of one child with clinical evidence of hepatic dysfunction in association with this syndrome. The patient whose case report is presented is a boy who was first seen at the age of 9 months. Steatorrhea (46.2 mmol fat/24 hr) was present. After stimulation of the pancreas with pancreozymin, no trypsin appeared in the duodenal juice, and the lipase level was very low (0.25 U/0.1 ml). The neutrophil level was 0.18-9.96 x 10^9/1. Skeletal abnormalities included rib and expansion and metaphyseal dysostosis. Immunological studies showed normal IgG levels, but reduced IgM (0.07 g/1) and only a trace of IgA. A needle liver biopsy taken at 2 yr showed variation in size of the hepatocytes and expansion of the portal tracts due to the presence of reticulin fibers. Among the other three cases, rib end expansion was present in one, metaphyseal dysostosis in two, and clinodactylyl hypoplasia in one. The serum IgA levels were 0.18, 5.8, and 0.54 g/1 in the three patients, resp; IgM levels were 0.78, 0.29, and 0.37, resp., and IgG levels were 3.8, 16.0, and 3.8 g/1, resp. All four patient were below the third centile in height and weight. This study illustrates the broad spectrum of the Shwachman-Diamond syndrome, and supports the contention that hepatic involvement should be regarded as a feature of the syndrome.

2464 VENO-OCCLUSIVE DISEASE OF THE LIVER AFTER CHEMOTHERAPY OF ACUTE LEUKEMIA: REPORT OF TWO CASES. (Eng.) Griner, P. F.; Elbadawi, A.; Packman, C. H. (Univ. Rochester Sch. Medicine and Dentistry, 601 Elmwood Ave., Rochester, NY 14642). *Ann. Intern. Med.* 85(5):578-582; 1976.

Two fatal cases of veno-occlusive disease of the liver after treatment of acute leukemia with cytosine arabinoside and 6-thioguanine are presented. In both patients (a 17-yr-old boy and a 74-yr-old man), upper right quadrant pain was preceded by anorexia, followed by the development of an enlarged tender liver, ascites, and evidence of collateral venous flow. The first patient had received 10 weeks of thioguanine and cytosine arabinoside treatment for acute myelomonocytic leukemia, and the second patient had been treated for acute myeloblastic leukemia for 12 weeks. The first patient also received daunomycin, vincristine, and cyclophosphamide; the only other drugs administered to the second patient were digoxin, fluazepam, and acetaminophen. Liver dysfunction was relatively mild. Antemortem and postmortem specimens of the liver showed changes characteristic of toxic veno-occlusive disease (i.e., a nonthrombotic, sclerotic, occlusive lesion of small hepatic veins, with congestion of related hepatic sinusoids, and commensurate atrophy of hepatic parenchyma). Neither the clinical syndrome nor the histologic features were consistent with the hepatic complications observed in acute leukemia. Similar findings have been described after the ingestion of certain plant alkaloids and after treatment with arsphenamine, urethane, and ionizing radiation to the liver. Since cytosine arabinoside and 6-thioguanine were the only agents received by both patients and because mild disturbances of liver cell function occasionally follow treatment with either agent, the cause of the hepatic lesions is thought to be one of these agents. The authors believe that 6-thioguanine is most likely responsible.

2465 ACUTE INTRAVASCULAR HEMOLYSIS AND ACUTE LIVER FAILURE ASSOCIATED AS A FIRST MANIFESTATION OF WILSON'S DISEASE. (Eng.) Roche-Sicot, J.; Benhamou, J. P. (Hopital Beaujon, 92110 Clichy, France). *Ann. Intern. Med.* 86(3):301-303; 1977.

The cases of three patients in whom the first manifestation of Wilson's disease was a syndrome in which acute intravascular hemolysis and acute liver failure were associated are presented. The patients included an 8-yr-old girl, a 13-yr-old boy, and a 15-yr-old girl. The syndrome developed in three periods; the first, lasting 3-14 days, was characterized by fatigue, fever, and jaundice; the second, lasting 1 or 2 days, was characterized by severe, acute intravascular hemolysis; and the third, lasting 2-6 days, was characterized by hepatic encephalopathy. All patients died from liver failure 7-21 days after the onset of the syndrome. The diagnosis of Wilson's disease was based on the presence of Kayser-Fleischer rings, the low value for ceruloplasmin (2-9 mg/dl), and the high value for hepatic copper (150-307 μg/g dry weight) in all three patients. The diagnosis of acute intravascular hemolysis was based on the sudden development of anemia, the high value for the reticulocyte count (195,000-450,000/mm^3), the absence of demonstrable bleeding, unconjugated hyperbilirubinemia, and the presence of hemoglobin in serum and urine. Hemolysis did not result from glucose-6-phosphate dehydrogenase deficiency or from autoantibodies, because the activity for that enzyme was normal, and the direct Coombs' test was negative. The syndrome of acute intravascular hemolysis and acute liver failure can be regarded as a characteristic manifestation of Wilson's disease.

2466 HEPATIC COPPER CONTENT, URINARY COPPER EXCRETION, AND SERUM CERULOPLASMIN IN LIVER DISEASE. (Eng.) Ritland, S.; Steinnes, E.; Skrede, S. (Natl. Hosp. Norway, Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(1):81-88; 1977.

Sixty-six patients, previously diagnosed as having other liver disorders, were screened for Wilson's disease. Increased hepatic copper content (>250 μg/g dry weight) was observed in 8 of 13 patients with primary biliary cirrhosis, but only normal or slightly elevated copper levels were present in other forms of cirrhosis, as well as acute hepatitis, steatosis of the liver, hepatic amyloidosis, hemochromatosis, and Gilbert's syndrome. Increased urinary copper excretion appeared more randomly among the various disorders in 14 patients, 6 of whom had normal liver copper concentrations. None of the patients had reduced plasma ceruloplasmin, and high ceruloplasmin levels were observed in almost all of the patients with significantly increased (>250 μg/g dry weight) hepatic copper concentrations. High levels were also associated with acute hepatitis, nonbiliary cirrhosis, and occasionally, with chronic active hepatitis. None of the liver disorders exhibited the combination of criteria frequently associated with Wilson's disease: low plasma ceruloplasmin levels, increased hepatic liver concentration, and high levels of urinary copper excretion.

Nonviral Hepatitis and Hepatic Injury

2479 ULTRASTRUCTURAL CHANGES IN ASPIRIN HEPATOTOXICITY. (Eng.) Iancu, T.; Elian, E. (Sharon Hosp., Petah-Tikva, Israel). *Am. J. Clin. Pathol.* 66(3):570-575; 1976.

The ultrastructural findings in a percutaneous liver biopsy specimen from a 9-yr-old boy who had elevated serum transaminase levels while receiving aspirin treatment for rheumatic fever are presented. The patient had been treated with 3.6 g of aspirin per day for 10 days and 3.0 g daily after that. The SGOT level was 220 mIU/ml, and the SGPT was 240 mIU/ml at the time that the serum salicylate level was 21 mg/ml. Extensive fine-structure changes of the hepatocytes, similar to those induced by hepatotoxic drugs, were seen at this time. These included marked dilatation of rough endoplasmic reticulum, proliferation of smooth endoplasmic reticulum, and mitochondrial abnormalities. The aspirin treatment was discontinued, and 1 month after discharge from the hospital, the patient showed no clinical or laboratory evidence of rheumatic fever or hepatic disease. The morphologic changes in this patient are thought to be evidence that aspirin is hepatotoxic. This study confirms the need for monitoring patients receiving systemic aspirin treatment by repeated transaminase measurements.

2480 LIVER DISEASE IN VINEYARD SPRAYERS. (Eng.) Cortez Pimentel, J.; Peixoto Menezes, A. (Universidade de Lisboa, Instituto de Anatomia Patologica, Avenida Professor Egas Moniz, Lisbon, Portugal). *Gastroenterology* 72(2):275-283; 1977.

Liver disease with inclusions of copper was recognized among 30 workers with "vineyard sprayer's lung"; the pathological findings of these patients are described, and the results of previous studies in which guinea pigs were exposed daily to aerosols of copper oxychloride (50% Cu) or oxychloride (37.5% Cu) plus zineb (16%) are briefly presented. The pathological findings in the workers were varied: focal or diffuse swelling and proliferation of Kupffer cells; histiocytic and sarcoid-like granulomata; fibrosis of variable degree in the perisinusoidal, portal, and subcapsular areas, accompanied by atypical proliferation of the sinusoidal lining cells; micronodular cirrhosis; angiosarcoma of the liver; and idiopathic portal hypertension. Abundant copper deposits were revealed by histochemical techniques within hepatic and pulmonary lesions in these patients. The observations on the human and experimental material suggest that the lesions described are related to copper sulfate exposure. A morphological resemblance was noted between the "liver disease of vineyard sprayers" and the hepatic lesions reported in workers exposed to inorganic arsenic and to vinyl chloride.

2481 COLITIS AND HEPATITIS CAUSED BY METHYLDOPA. (Eng.) Bonkowsky, H. L.; Brisbane, J. (Veterans Admin. Hosp., White River Junction, VT 05001). *JAMA* 236(14):1602-1603; 1976.

The case of a 55-yr-old man in whom acute, reversible hepatitis and colitis developed after methyldopa therapy is presented. The patient had received antihypertensive therapy with hydrochlorothiazide (100 g/day) for 6 days, after which methyldopa (250 mg, t.i.d., p.o.) was added to the treatment regimen. Seven days later, the patient presented with fever, bloody diarrhea, and a symmetrically distributed erythematous macular rash on the back and flanks. Proctoscopy and mucosal biopsy specimens revealed mucosal inflammation. The liver was palpable, the SGOT level was 150 Karmen U/ml, and total bilirubin was 2.3 mg/100 ml. Nine days after discontinuing all medication, all symptoms had cleared, and the liver function tests returned to normal. The symptoms reappeared for 48 hr after the patient had taken 50 mg of hydrochlorothiazide and 250 mg of methyldopa. Hydrochlorothiazide therapy was resumed without adverse effects. It appears that methyldopa can produce acute colitis, as well as the previously recognized hepatitis, by an allergic reaction.

2482 ORAL METHIONINE IN THE TREATMENT OF SEVERE PARACETAMOL (ACETAMINOPHEN) OVERDOSE. (Eng.) Crome, P.; Volans, G. N.; Vale, J. A.; Widdop, B.; Goulding, R. (Guy's Hosp., London SE1 9RT, England). *Lancet* 2(7990):829-830; 1976.

The use of methionine as an alternative to cysteamine in the treatment of 30 patients at risk of hepatic damage from paracetamol overdose was evaluated. Methionine was given p.o. at 2.5 g/4 hr, up to a total of 10 g. The patients received the first dose within 10 hr of overdose. There were no deaths, and no reports of hepatic encephalopathy or other complications. In 3 patients, the maximum plasma aspartate aminotransferase exceeded 1,000 IU/1, in 6 it was 35-250 IU/1, and in the remaining 21 patients it remained normal. These results suggest that methionine may be effective in reducing the frequency and severity of paracetamol-induced liver damage and may provide an effective nontoxic alternative to cysteamine.

2483 INTRAHEPATIC CHOLESTASIS FOLLOWING THE USE OF ATROMID-S. (Eng.) Valdes, M.; Jacobs, W. H. (Menorah Medical Center, Kansas City, MO). *Am. J. Gastroenterol.* 66(1):69-71; 1976.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

484 HEPATITIS A. (Eng.) Maynard, J. E. (Bureau of Epidemiology, Center for Disease Control, U.S. Public Health Service, 4402 North eventh St., Phoenix, AZ 85014). *Yale J. Biol. Med.* 9(3):227-233; 1976.

Etiologic and epidemiologic aspects of hepatitis A are discussed. Hepatitis A is a disease of worldwide distribution, which occurs in endemic and epidemic form and is transmitted primarily by person-to-person contact through the fecal-oral route.

Fecal carriers of the virus who are asymptomatic or are in the preclinical stages of the disease are major contributors to the spread of infection. Common source epidemics due to water and milk have been observed, and food-borne outbreaks of hepatitis A are relatively common. Hepatitis A-associated viral-like particles have been visualized by immune electron microscopic techniques in early acute-illness-phase stools of humans with hepatitis A, as well as in chimpanzees experimentally infected with hepatitis A virus-containing material. The particles are spheres of approximately 27-nm diameter and are surrounded by halos, which represent specific hepatitis A antibody interacting with virus. Laboratory techniques for the diagnosis and seroepidemiologic investigation of hepatitis A include complement fixation and immune adherence tests. The morphologic and immunologic similarity of the various classes of particles referred to as hepatitis A antigen, together with the consistency in worldwide epidemiologic patterns for the disease, suggest that hepatitis A is caused by a single viral agent lacking the heterogeneity of hepatitis B virus structural components and that there may be a relative antigenic homogeneity between strains of virus recovered from various parts of the world. Serologic studies indicate that hepatitis A virus is not a major contributing cause in post-transfusion hepatitis.

2485 VIRAL HEPATITIS, TYPE A: ETIOLOGY AND EPIDEMIOLOGY.

(Eng.) Dienstag, J. L.; Purcell, R. H. (Massachusetts General Hosp., Boston, MA 02114). *Rush-Presbyt. St. Luke's Med. Bull.* 15(2):104-114; 1976.

The etiology and epidemiology of viral hepatitis A is reviewed. Studies in man and nonhuman primates during the previous 30 yr provided a groundwork for the current acceleration in the understanding of type A hepatitis. Recently, a 27-nm virus-like particle, designated hepatitis A antigen (HA Ag), was detected in stools of patients with acute type A viral hepatitis and, subsequently, in the sera and livers of infected marmosets. The discovery of HA Ag was instrumental in the development of several *in vitro* diagnostic tests to identify both antigen and antibody. With these new techniques, it has been possible to characterize and purify HA Ag particles to demonstrate the transmission of hepatitis A virus in chimpanzees, to test the susceptibility of other nonhuman primates, and to study the immunology and seroepidemiology of hepatitis A virus infection. Evidence accumulating from these studies suggests that HA Ag is the etiologic agent of type A viral hepatitis. In addition, seroepidemiologic investigations with these new diagnostic techniques have identified a new category of viral hepatitis unrelated to either hepatitis A or B viruses, so called "non-A, non'B" hepatitis.

2486 ANTIBODY TO HEPATITIS A ANTIGEN IN INSTITUTIONALIZED MENTALLY RETARDED PATIENTS.

(Eng.) Szmuness, W.; Purcell, R. H.; Dienstag, J. L.; Stevens, C. E. (New York Blood Center, 310 E. 67th St., New York, NY 10021). *JAMA* 237(16): 1702-1705; 1977.

The sera of patients with Down's syndrome and matched controls with other causes of mental retardation were tested by immune adherence hemagglutination for the presence of antibody to hepatitis A antigen (anti-HA). Among a total of 233 patients tested, 175 were anti-HA positive (75.1%). Patients with Down's syndrome had almost exactly the same rate of anti-HA positivity (73.7%) as those with mental retardation caused by other factors (76.5%). There were no sex or age differences. Patients reactive for hepatitis B surface antigen (HBsAg) or its antibody (anti-HBs) were reactive for anti-HA more frequently than those with a negative reaction for these markers (87% with HBsAg and 77% with anti-HBs versus 61%). The rate of anti-HA positivity was closely correlated with the duration of institutionalization: of 80 patients who had been institutionalized for less than 3 yr, 61.2% were anti-HA positive, whereas 82.4% of 153 patients institutionalized for 3 yr or longer were anti-HA positive. In contrast to serologic markers of hepatitis type B, the prevalence of anti-HA does not depend on the cause of mental retardation or on the age at primary infection. This study confirms that many closed institutions for the mentally retarded are hyperendemic for hepatitis type A and that formation of anti-HA is not greatly affected by either immune deficiency or immune immaturity.

2487 ACTION OF A NEW ANTIVIRAL DRUG ON THE HEPATITIS B ANTIGEN (HBAg) IN PATIENTS WITH VIRAL HEPATITIS AND ON HEALTHY CARRIERS.

(Por.) de Padua Vilela, M.; Siqueira, W. A.; Rodrigues, L. D.; Domingues, S. H. S.; dos Santos Rodrigues, F. (Escola Paulista de Medicina, Sao Paulo, Brazil). *Rev. Bras. Clin. Ter.* 3(7):251-254; 1975.

Results of clinical trials of the activity of ribavirin on the hepatitis B antigen (HBAg) in 5 patients with viral hepatitis and in 17 healthy subjects (carriers) with positive HBAg antigenemia are reported. The HBAg titers were determined by reverse immunoelectrophoresis during the week preceding and the week following the treatment. Among the patients with hepatitis, the treatment (100 mg t.i.d. x 12, p.o. in 2/5; 200 mg t.i.d. x 20, p.o., in 2/5; 100-200 mg t.i.d. or q.i.d. x 10-30, p.o., in 1/5, for a total dose of 40 g for 3 courses) resulted in negative HBAg immunologic response in 3/3 with chronic hepatitis and 1/2 with prolonged hepatitis, and decreased response in 1/2 with prolonged hepatitis. Among the carriers, the treatment (100 mg q.i.d. x 10 in 6; 200 mg t.i.d. x 20 in 11) resulted in negativity of the HBAg titer in three, decreased titer in six, and unchanged immunologic response in eight. The tolerance was good and no side-effects were noted. In spite of the encouraging results obtained, the authors stress the necessity of further investigations to determine the transitory or permanent character of the results. The possibility of clinical trials with higher doses is considered.

488 VIRAL HEPATITIS, TYPE B. (Eng.) Barker, L. F. (Bureau Biologics, Food and Drug dmin., Bethesda, MD 20014). *Yale J. Biol. Med.*)(3):235-241; 1976.

epatitis B virus (HBV) is discussed in terms of s clinical features, epidemiology, detection, d cure or prevention. The presumptive infectious rm of HBV is a 40-42-nm Dane particle, which consists of an inner nucleocapsid core antigen (HBcAg) d an outer lipoprotein surface antigen (HBsAg). e interval between exposure and appearance of etectable serum HBsAg is related to the infectivity iter of the inoculum and probably to the exposure ute. HBsAg appears in the serum days or weeks efore clinical signs and symptoms appear. Antibody ctivity against HBcAg (anti-HBc) appears during e acute illness, while HBsAg is still present. e HBV carrier state, manifested by the persistence HBsAg and anti-HBc and the absence of detectable tibody against HBsAg (anti-HBs), develops in an stimated 5-10% of the infected adults in the United tates. The commonest modes of HBV spread are robably from infected mothers to infants and from e family member to another by close personal ntact. The most sensitive methods for detecting V antigens and antibodies are radioimmunoassays. most as sensitive are the following hemagglutination techniques: passive hemagglutination for anti-s detection, reversed passive hemagglutination r HBsAg detection, and immune adherence hemaglutination for anti-HBc detection. High titer epatitis B immunoglobulin appears to be capable giving partial and temporary protection against V infection, and experimental vaccines consisting formalin-treated HBsAg purified from human plasma ve provided protection against challenge with HBV susceptible chimpanzees.

89 HEPATITIS AMONG PLASMA FRACTIONATION WORKERS. AN INDUSTRY-WIDE STUDY. (Eng.) hen, S. R.; Butler, G. J.; Shmunes, E.; Holmes, W. (Natl. Inst. Occupational Safety and Health, bert Taft Lab., 4676 Columbia Parkway, Cincinnati, 45226). *J. Occup. Med.* 18(10):685-689; 1976.

survey of 14 plasma fractionation facilities in e United States was conducted during 1973-74 to sess the extent of hepatitis infection among rkers. Among 12 facilities responding to the rvey, 10 were engaged in the production of immune rum globulin (γ-globulin). The majority of fraconators were also involved in the manufacture of bumin (67%), tetanus immune globulin (67%), and tihemophilic factor (50%). In 1973, every fraconation facility in operation for longer than 1 had experienced clinical cases of viral hepatitis. total of 61 employees working in full-time posions with blood derivatives contacted hepatitis. ve facilities (36%) reported 25 cases of clinical patitis among employees with fringe-contact posure to blood products (i.e., less than 8 hr/ y of exposure). There were 43 (71%) full-time actionators who were employed as plasma poolers. the workers in full-time and fringe groups, 48% d 32%, resp., had participated in an immune serum obulin prophylaxis program prior to the onset of their clinical disease. The above data suggest that there is a high risk of hepatitis among plasma fractionation workers.

2490 HEPATITIS B (SURFACE) ANTIGEN AND VIRAL HEPATITIS IN FAMILY CONTACTS OF ACUTE HEPATITIS B PATIENTS. (Eng.) Farnik, J.; Beranova, I.; Vilim, V.; Dbala, D.; Vesely, V.; Jindra, J.; Zakova, M. (Inst. Microbiology and Epidemiology, Charles Univ., Marxova 13, 30599 Plzen, Czechoslovakia). *Zentralbl. Bakteriol.* [*Orig. A*] 236(2/3): 199-204; 1976.

Four hundred sixty-five family contacts of acute hepatitis B patients were followed up, and 344 were tested for the presence of hepatitis B surface antigen (HBsAg) at the time of the hospitalization of the index case and again after 3 months. The families were followed for a total of 6 months. Nineteen of 418 persons screened for the first time were HBsAg-positive, and 2 of these were hospitalized with acute inflammatory liver disease. The highest percentage of HBsAg-positive persons was found in the families of patients without a history of parenteral exposure. Five family contacts were hospitalized 2-4 months following the admission of the index patient. All were spouses of the index patients, and none had a history of parenteral exposure other than blood sampling for this study. Two cases of previously undetected antigenemia were found among the 344 contacts screened in the 3-month period.

2491 MOTHER-TO-INFANT TRANSMISSION OF HEPATITIS B VIRUS AND ITS CONSEQUENCES. REPORT OF A CASE AND REVIEW OF THE LITERATURE. (Fre.) Bugnon, B.; Brette, R. (Hopital Edouard-Herriot, Pavillon H, place d'Arsonval, F 69374 Lyon Cedex 2, France). *Arch. Fr. Mal. App. Dig.* 64(8):667-670; 1975.

A case of mother-child hepatitis B virus transmission and its effect on the child are discussed. A 23-yr-old woman was infected with viral hepatitis at the onset of pregnancy. Diagnosis was based on increased (up to 1,100 U) glutamino-pyruvic transaminase levels and the presence of HBsAg in the serum, as assessed by immunodiffusion and electroimmunodiffusion; the hepatitis developed into chronic persistent hepatitis. The infant's examination for HBsAg in the blood of the umbilical cord was positive by radioimmunologic dosage and reverse hemagglutination. Moderately higher transaminase levels and slight hepatomegaly from the age of 1.5 months suggested subclinical infection. The child's infection could have occurred by mouth or parenterally at the time of delivery or prenatally through the amniotic fluid, or on the interior surface of the placenta; the presence of Dane's particles in the blood of the umbilical cord proved the possibility of transplacental transmission. The baby's infection and resulting liver damage was sometimes clinically obvious and sometimes at a subclinical level. The virus can persist up to 39 months in affected infants. Many of them, with no biological liver disorder, should be considered as healthy carriers. Histological changes in the infant consisted of ballooning liver cells (cobblestone pattern), necrotic foci, and portal lymphoid hyperplasia. In view of the absence of effective treatment of these cases of hepatitis, efforts should essentially concentrate on the prevention of neonatal infection, with specific anti-HBsAg γ-globulin therapy at birth.

2492 VIRAL HEPATITIS TYPE B DURING PREGNANCY, THE NEONATAL PERIOD, AND INFANCY. (Eng.)

Gerety, R. J.; Schweitzer, I. L. (DBBP, Bureau Biologics, FDA, 8800 Rockville Pike, Bethesda, MD 20014). *J. Pediatr.* 90(3):368-374; 1977.

The diagnostic and prognostic significance of three hepatitis B-associated antigens and antibodies in the development of the chronic carrier state in infants was assessed. Eighteen women who developed type B hepatitis late in pregnancy or early in the postpartum period (groups I and II), 12 women who were chronically infected with the hepatitis B virus (groups III and IV), and 32 of their offspring were tested for hepatitis B surface antigen (HBsAg), antibody to HBsAg, antibody to the hepatitis B core antigen, and for the hepatitis B-associated e antigen and its antibody. Twelve of 18 infants born to group I and group II mothers and 5 of 14 infants born to group III and group IV mothers became chronically infected with hepatitis B virus (HBV); the outcome did not appear to be influenced by maternal anti-HBc titers, by antigen subtype, by the presence or absence of HBsAg in the cord sera, or by the infants' birth weights or gestational ages. The presence of maternal e antigen did correlate with the development of chronic HBV infections in the infants studied. The e antigen appeared in five infants born of e antigen-negative mothers, but did not appear to be associated with the morbid prognosis that generally accompanies its presence in adult HBsAg carriers. The data also suggest that maternal anti-e may favor HBsAg clearance and recovery in neonatally acquired HBV infections.

2493 PREGNANCY HEPATITIS IN LIBYA. (Eng.)

Christie, A. B.; Allam, A. A.; Aref, M. K.; El Muntasser, I. H.; El-Nageh, M. (2 Beach Lawn, Liverpool L22 8QA, England). *Lancet* 2(7990):827-829; 1976.

The incidence and death rate of hepatitis in pregnant women in Libya were studied. Of 922 hepatitis patients treated during 1975, 377 were men and 545 were women. The fatality rates were 0.53% and 7.67%, resp. The death rate in pregnant women (12.97%) was much higher than that in nonpregnant women (1.6%). Among the 36 fatal cases in which the month of pregnancy was noted, 25 deaths occurred in the last trimester, and 30 of the 34 deaths occurred during the last 4 months of pregnancy. Although 18.4% of the male patients and 15.2% of the women were hepatitis B surface antigen-positive, no patient shown to be antigen-positive died. The frequency of hepatitis in the second half of the year fell both in pregnant women and in the general population, suggesting a waning hepatitis B epidemic. Because all the men claimed to eat a full balanced diet with ample animal protein and the women said their diet was mostly carbohydrate, the high mortality rate among the pregnant women may have had a nutritional basis.

2494 MULTIPLE HEPATITIS VIRUSES IN MULTIPLE ATTACKS OF ACUTE VIRAL HEPATITIS. (Eng.)

Mosley, J. W.; Redeker, A. G.; Feinstone, S. M.; Purcell, R. H. (John Wesley County Hosp., 2826 S. Hope St., Los Angeles, CA 90007). *N. Engl. J. Med.* 296(2):75-78; 1977.

The causes of 30 episodes of acute viral hepatitis were investigated in 13 patients who had multiple attacks. Two of 30 bouts were caused by hepatitis A virus, and 12 by hepatitis B virus. No patient, however, had more than one attack with the serologic characteristics of type A or type B disease. Thus, there were 16 bouts (53%) not attributable to either of the two recognized hepatitis viruses. None of these "non-A, non-B" episodes, evaluated for infectious mononucleosis and cytomegalovirus infection, could be ascribed to either. It appears that the clinical syndrome of viral hepatitis is produced not only by hepatitis A and B viruses, but also by two other agents.

2495 HEPATITIS B ANTIGEN: A REVIEW OF ITS IMPORTANCE IN THE PRACTICE OF OBSTETRICS AND GYNECOLOGY. (Eng.)

Babb, R. R. (Palo Alto Medical Clinic, 300 Homer Ave., Palo Alto, CA 94301). *Am. J. Obstet. Gynecol.* 126(5):602-606; 1976.

The importance of the hepatitis B antigen (HBAg) serologic test in obstetrics and gynecology is reviewed. HBAg has been demonstrated in patients with acute and chronic hepatitis and also in clinically healthy persons; the incidence of the antigen in blood donors ranges from 0.1 to 0.5%. Viral hepatitis is an occupational hazard for medical personnel, and those with a positive test are potentially infectious. Infants born to mothers who are either HBAg carriers or ill with hepatitis B may become HBAg positive and develop chronic hepatitis. The risk of a neonate becoming HBAg positive depends on the stage of intrauterine development when exposure to the virus occurred. Acute hepatitis B infection near term is associated with the highest risk. Of 158 babies born to healthy hepatitis B surface antigen (HBsAg) carriers, 63 became antigen positive within a few months of birth. Three factors appear to increase the chance of developing antigenemia in these babies: the HBsAg titer in the mother's blood, the presence of HBsAg in cord blood, and a positive HBsAg test in siblings' blood. The route of infection is related to both transplacental transmission of the virus and ingestion of contaminated material at the time of delivery. Once HBAg positive, the infants generally remain so.

2496 OCCURRENCE OF SUBTYPES OF HEPATITIS B ANTIGEN IN ACUTE HEPATITIS AND CHRONIC LIVER DISEASES. (Hun.)

Buki, B.; Szalay, F.; Nagylucskay, S.; Schvaab, E. (I. Belgyogyaszati Klinika, Semmelweis Orvostudomanyi Egyetem, Budapest, Hungary). *Orv. Hetil.* 116(27):1567-1569; 1975.

occurrence of *ad* and *ay* subtypes of hepatitis
ntigen was studied by immunoelectro-osmophoresis
the sera of 510 patients with HBsAg-positive acute
atitis, of 853 patients infected with B virus hep-
tis in epidemic foci, and of 113 patients with
onic liver diseases. Subtype *ad* was detected in
of the 510 patients with acute viral hepatitis;
ay subtype was found in 281. Subtype *ad* was found
138/353 icteric patients, and subtype *ay* in 215/353;
incidences of *ad* and *ay* were 91/157 and 66/157
anicteric patients, resp. Subtype *ad* was found
126/268 men, and *ay* in 142/268. In women, *ad* was
nd in 103/242, and *ay* in 139/242. The incidence of
two subtypes was nearly equal under the age of
yr, while *ay* was slightly more frequent in pa-
nts aged over 21 yr. Two hundred sixty-one
ients were re-examined during the convalescence;
of them had the *ad* subtype, and 174 had the *ay* sub-
e during the acute period; 20 patients remained
Ag-positive, with 6 having *ad*, and 14, *ay*. Five
dred twenty-nine patients were infected by sources
ing the *ay* subtype; all patients were found to
e the *ay* subtype, while 1 of the 324 patients
ected by an *ad* source had the *ay* subtype. Thirty-
of the 113 patients with chronic liver disease
e HBsAg-positive, 7 had subtype *ad*, and 24 had *ay*.
patient with subtype *ad* and 6 with *ay* were
nd among 35 patients with chronic persisting
atitis. Fourteen of the 26 patients with crypto-
ic cirrhosis were positive; 4 had subtype *ad*, and
subtype *ay*. One patient with *ad* and another with
were found among 13 patients with alcoholic fatty
eneration. One patient with *ad* and 2 with *ay*
e found among 20 patients with alcoholic cirrhosis.
ee patients had subtype *ay* among 19 patients
h other liver diseases (secondary biliary cirrho-
, chronic cholangiohepatitis, cholestasis of
gnancy, unidentified toxic hepatic lesions).

7 AN EPIDEMIC OF INFANTILE PAPULAR ACRODERMATITIS (GIANOTTI'S DISEASE) IN JAPAN OCIATED WITH HEPATITIS-B SURFACE ANTIGEN SUBTYPE

. (Eng.) Ishimaru, Y.; Ishimaru, H.; Toda, G.;
a, K.; Mayumi, M. (Ishimaru Pediatric Clinic,
suyama City 790, Japan). *Lancet* 1(7962):707-
; 1976.

epidemic of infantile papular acrodermatitis
A) in Japan is reported. Between October, 1974
September, 1975, the disease was diagnosed in
children on the basis of the following symptoms:
-itching, erythematous papular dermatitis on the
e and extremities; inguinal and axillar lymph
e enlargement; hepatomegaly; and abnormal liver
ction tests. Eighty-eight percent of the patients
e less than 3 yr old. In the 54 patients tested,
were hepatitis B surface antigen (HBsAg)-positive
determined by an immune adherence hemagglutina-
n method), whereas only 3 of 43 mothers, 1 of 37
hers, and 7 of 27 siblings of these patients were
igen-positive. HBsAg was found in the serum of
majority of patients when tested on the first
of skin eruption (25 of 27 cases). Antibody to
Ag (anti-HBs) was not detected in any of the pa-
nts with IPA. The exposure rate (the percentage
individuals with either HBsAg or anti-HBs) was
9% in patients, 40.7% in siblings, 19.1% in mothers, and 10.9% in fathers; anti-HBs occurred in 14.8%, 11.6%, and 8.1% of the siblings, mothers, and fathers, resp. HBsAg subtype *ayw* was identified by a hemagglutination-inhibition method in 42 of 48 patients, whereas this subtype was detected in only 3 of 7 siblings, in none of 4 mothers and fathers, and in none of 168 symptom-free blood donors with HBs antigenemia. Subtype *adr* was found in 3 of the 48 patients, and *adw* was not found. Because subtype *ayw* and IPA are extremely rare in Japan, the association of the disease with HBsAg subtype *ayw* is considered to be extremely significant. The immature immunological status of these patients may have influenced the development of the clinical manifestations.

2498 POST-TRANSFUSION HEPATITIS: THE ROLE OF HEPATITIS B ANTIBODY.

(Eng.) Koretz, R. L.; Overby, L. R.; Gitnick, G. L. (Center Health Sciences, Univ. California, Los Angeles, CA 90024). *Gastroenterology* 70(4):556-561; 1976.

The question of whether transfusion of hepatitis B surface antibody (anti-HBs) positive blood would contain undetectable amounts of hepatitis B surface antigen (HBsAg), thereby increasing the risk of hepatitis B, or whether it would provide a protective effect against post-transfusion hepatitis (PTH) was studied. Various groups of patients were screened and found to have received transfusions of either HBsAg positive or anti-HBs positive blood, both of these (given at different times), or transfusions of blood that were negative for each. Commercial blood was much more likely to contain anti-HBs than was volunteer blood. Patients who received higher titers of antibody tended to receive more units of blood, with more of this blood coming from commercial sources, making interpretation of the data difficult. Infusion of anti-HBs was not protective against PTH or hepatitis B events. Indeed, infusion of high titers of anti-HBs was associated with an increased incidence of hepatitis B. These data are consistent with the theory that some anti-HBs positive units of blood contain small amounts of infective HB virus.

2499 HERPESVIRUS HOMINIS HEPATITIS AND DISSEMINATED INTRAVASCULAR COAGULATION: OCCURRENCE IN AN ADULT WITH PEMPHIGUS VULGARIS.

(Eng.) Keane, J. T.; Malkinson, F. D.; Bryant, J.; Levin, S. (Rush-Presbyterian-St. Luke's Medical Center, 1753 W. Congress Parkway, Chicago, IL 60612). *Arch. Intern. Med.* 136(11):1312-1317; 1976.

A case of herpesvirus hominis (HVH) hepatitis in a 36-yr-old woman who had received prednisone therapy for pemphigus vulgaris continuously for 7 yr is reported. The patient presented with multiple oral and genital erosions, abdominal pain, and lethargy; hematemesis and guaic-positive stools developed. Moderate right upper quadrant tenderness without hepatomegaly was noted, and bowel sounds were hypoactive. After an acute terminal illness that was characterized by fulminant hepatic failure and disseminated intravascular coagulation, postmortem examination revealed massive hepatic necrosis.

herpesvirus (type 1) was isolated from the liver. The ten previously reported cases of HVH hepatitis in adults are reviewed. Greater awareness of the clinical manifestations of HVH hepatitis should lead to early diagnosis, although successful modes of therapy await development.

LIVER AND BILIARY TRACT

Chronic Hepatitis

2523 CHRONIC ACTIVE HEPATITIS IN HEPATITIS B SURFACE ANTIGEN (HBsAg) CARRIERS: THE NEED FOR LIVER BIOPSY. (Eng.) Sampliner, R. (Veterans Admin. Hosp., 3900 Loch Raven Blvd., Baltimore, MD 21218). *JAMA* 237(1):50-51; 1977.

The cases of patients with chronic active hepatitis discovered during routine screening for hepatitis B surface antigen (HBsAg) for blood donation are presented. Only one patient had sought medical attention prior to the discovery of hepatitis B antigenemia, and her problem had not been recognized at that time. The liver biopsy findings included piecemeal necrosis (1 patient), bridging necrosis (1 patient), and chronic active hepatitis and cirrhosis (2 patients). SGOT ranged from 87 to 810 U/ml and SGP from 154 to 573 U/ml in these four patients; the maximum globulin levels in three of the patients were 3.5, 0.84, and 1.72 g/100 ml. One patient was asymptomatic, one had only a 1-month history of easy fatigability initiated by 1 week of intermittent vomiting, and the third patient had a 1-yr history of easy fatigability. The fourth patient had been exposed to hepatitis 2 months prior to the detection of HBsAg and was asymptomatic at this time. He was also e-antigen-positive. Both antigens persisted for 19 months, and he subsequently developed clinical icteric hepatitis. Because clinically occult liver disease can be histologically severe, liver biopsy is indicated when liver enzyme levels are persistently abnormal in long-term HBsAg carriers.

2524 CLINICAL AND IMMUNOLOGICAL OBSERVATIONS IN HEPATITIS B ANTIGEN-POSITIVE AND HEPATITIS B ANTIGEN-NEGATIVE CHRONIC ACTIVE HEPATITIDES. (Hun.) Par, A.; Bajtai, G.; Barna, K.; Gogl, A.; Patakfalvi, A.; Balazs, M.; Miszlai, Zs. (I. Belgyogyaszati Klinika, Pecsi Orvostudomanyi Egyetem, Pecs, Hungary). *Orv. Hetil.* 116(30):1743-1747; 1975.

Clinical, biochemical, and immunological findings in 24 patients with hepatitis B antigen (HBAg)-positive and in 24 patients with HBAg-negative chronic persistent hepatitis are presented. Long-term remission was achieved by prednisolone or prednisolone plus azathioprine in 18 patients in the HBAg-positive group, and in 15 of the HBAg-negative patients, the disease progressed in 2 and 3 patients, resp. Four HBAg-positive and six HBAg-negative patients died. Anamnestic data suggestive of viral hepatitis were found in two-thirds of the HBAg-positive patients, and the disease had an acute onset in about the same number of patients; the primary chronic form was more frequent among the HBAg-negative patients. The incidence of liver cirrhosis at diagnosis was higher in the HBAg-negative group. Hematological findings such as erythrocyte sedimetation reactions >20 mm/hr, RBC $<3.5 \times 10^6$, and WBC <4,000 were more frequent in the HBAg-negative group. The incidence of considerably increased serum alkaline phosphatase was also higher in this group. The IgG level was 146% of the normal value in the HBAg-positive group, versus 180% in the negative group ($p<0.1$). The IgM level averaged 143% of the normal level in the positive group, versus 121% in the negative group; however, the IgM level was below normal in many patients in both groups. The humoral and cellular autoimmune reactions showed no marked differences between the two groups. The findings indicate the role of immunological factors in the pathogenesis of both forms of chronic persisting hepatitis, in spite of the clinical, biochemical, and etiological differences.

2525 POST-TRANSFUSION CHRONIC LIVER DISEASE. (Eng.) Koretz, R. L.; Suffin, S. C.; Gitnick, G. L. (Center for the Health Sciences, Univ. California, Los Angeles, CA 90024). *Gastroenterology* 71(5):797-803; 1976.

Forty-seven patients with post-transfusion hepatitis were followed prospectively from transfusion to document the sequelae of acute hepatitis among recipients of commercial and volunteer blood and to assess factors influencing the development of chronic hepatitis (CH). Twenty-nine patients had SGPT levels elevated at least twofold for more than 20 weeks; they were classified as CH. When the patients with CH were compared with those with only acute hepatitis (abnormal SGPT for less than 20 weeks), no difference was found with respect to age, sex, number of units transfused, incubation period, presence or absence of symptoms, occurrence of jaundice, maximum SGPT, receipt or development of hepatitis B surface antigen or antibody, underlying illness, or area of the hospital where the patient was treated. Liver biopsies in 15 of the 29 revealed chronic active hepatitis in 9, chronic persistent hepatitis in 2, and unresolved hepatitis in 4. Five of the nine patients with chronic active hepatitis had no symptoms. None of these died or have developed cirrhosis. Because chronic liver disease frequently developed after acute post-transfusion hepatitis among multiply transfused hepatitis B surface antigen-negative blood recipients, close follow-up, including liver biopsy, is warranted in such patients with prolonged transaminase elevations.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

2530 INFLUENCE OF IRON FROM WINE ON THE DEPOSITS OF THIS METAL IN CHRONIC ALCOHOLICS. (Spa.) Miralles Garcia, J. M.; de Castro del Pozo, S. (Catedra de Patologia General, Salamanca, Spain). *Med. Clin. (Barcelona)* 64(6):284-289; 1975.

The relation of ingested iron from wines or distilled beverages to tissue iron storage was investigated in 48 chronic alcoholics; 47 subjects were wine drinkers. Twenty-four cases showed hepatic lesions, and four showed hepatitis. Clinical studies in alcoholics included: detailed anamnesis, beverage iron determination, histochemical determination of hepatic siderosis, hepatic iron determination (494.96 ± 143.75 mg/100 g), desferrioxamine-B test (1.33 ± 1 mg), and diethylenetriamine pentaacetic acid test (0.44 ± 55 mg). Although the only three cases of hemochromatosis with siderosis 4 had no history of alcoholism, they showed the highest liver and urine iron levels. For 17 controls, hematology showed iron, desferrioxamine-B and the pentaacetic acid to be 115 ± 56.38 mg/100 g, 1.10 ± 0.58 mg and 0.21 ± 0.08 mg, resp., with no cases of siderosis exceeding grade 1. The relation between hepatic iron concentrations in alcoholics and controls was significant ($p<0.1$).

2531 GASTRIC CLEARANCE OF SERUM ALBUMIN IN PATIENTS WITH ALCOHOLIC LIVER CIRRHOSIS. (Eng.) Andre, C.; Descos, F.; Descos, L.; Lambert.

R.; Bory, R. (U-45, INSERM, Hopital Edouard-Herriot, Pavillon H, F-69374 Lyon Cedex 2, France). *Digestion* 14(4):357-359; 1976.

To examine the possibility that plasma leakage through an abnormal digestive mucosa might contribute to hypoalbuminemia in liver cirrhosis, gastric albumin clearance studies were carried out in 26 patients with alcoholic liver cirrhosis and in 10 controls. An esophagogastroscopy with gastic fundal and antral biopsies was performed in each patient, and gastritis was estimated histologically. The serum albumin concentration was measured by the single-radial immunodiffusion method in the gastric secretion, buffered with glycine; the buffer contained phenol red as a dilution indicator. The mean gastric clearance of serum albumin in controls was .03 ml plasma/30 min; the clearance in the cirrhotic patients was more than twice as high, 2.08 ml/0 min (p<0.01). Increased gastric protein loss occurred only in the 15 patients with gastritis. The presence of distended esophageal varices (15 patients) did not influence protein loss. The results support the suggestion that plasma leakage through an abnormal digestive mucosa contributes to hypoproteinemia in liver cirrhosis.

532 ACUTE ALCOHOLIC HEPATITIS. (Hun.) Herics, M.; Keresztury, S.; Nagy, Gy.; ollath, Z. (Miskolci Semmelweis Korhaz I. Ferto-oosztaly, Miskolc, Hungary). *Orv. Hetil.* 116(45): 657-2660; 1975.

iochemical, clinical, and diagnostic aspects of 3 cases of acute alcoholic hepatitis are discussed. ll patients were chronic alcoholics; most of them ad increased their daily intake of alcohol during he last days or weeks before the onset of the isease. Loss of appetite, nausea, abdominal pains, aundice, and considerable enlargement and tenderess of the liver were seen in all cases. The biliubin level was increased by 3.1-24.5 mg%, due to ncreased direct bilirubin level. A moderate inrease was seen in the transaminase level in 31 ases. An increased serum alkaline phosphatase evel was found in 26 patients. The serum protein evel was below 5.6 g% in 44 cases. The serum gnesium level was decreased in 11/13 cases invesigated. The WBC count was increased in 50 cases. e thrombocyte count was below normal in 16 cases, d the prothrombin level was below normal in 31 cases. Three-fourths of the patients had temperatures of up to 39 C during the first 2-6 weeks. The length of the hospitalization ranged from 28 to 136 days. Five patients, including two women, died; the cause of death was acute hepatic insufficiency in four cases and hepatorenal syndrome in one. Therapy consisted of abstinence, protein-rich diet, vitamins, magnesium, folic acid, plasma transfusion, diuretics, and steroids. Two patients developed cirrhosis after 4 months of treatment. The histological examination of the biopsy specimens revealed proliferation of fibroblasts and connective tissue cells, round-cell infiltration, usually severe fatty degeneration, iron pigment in 70-80% of Kupffer's cells, leukocyte and mononucleate infiltration in the portal region and lobuli, and massive necrosis superimposed on the chronic changes typical of chronic alcoholism.

2533 THE NATURAL HISTORY OF GASTROINTESTINAL BLEEDING IN PATIENTS WITH ALCOHOLIC CIRRHOSIS. DEFINITION OF A SUBGROUP OF PATIENTS WITH HIGH RISK OF BLEEDING RECURRENCE [Abstract]. (Eng.) Degos, F.; Rueff, B.; Benhamou, J. P. (Hopital Beaujon, Clichy, France). *Digestion* 14(5/6):464; 1976.

2534 BLOOD LIPOPROTEINS IN FATTY LIVER [Abstract]. (Eng.) Brixova, E.; Niederland, T. R. (Comenius Univ., Sch. Medicine, Bratislava, Czechoslovakia). *Digestion* 14(5/6):500; 1976.

2535 HISTOCOMPATIBILITY ANTIGENS IN ALCOHOLIC CIRRHOSIS [Abstract]. (Eng.) Bailey, R. J.; Krasner, N.; Eddleston, A. L. W. F.; Williams, R.; Batchelor, J. R.; Kennedy, L. A. (King's Coll. Hosp. and Medical Sch., London, England). *Digestion* 14(5/6):496; 1976.

LIVER AND BILIARY TRACT

Cirrhosis

536 NEW THERAPY FOR HEPATARGIA AND HEPATIC COMA. (Por.) Martins, J.; Nogueira, F.; tos, M. L.; Peneda, J. (Hospital de Santo Antonio s Capuchos, Lisbon, Portugal). *Bol. Clin. Hosp. vis Lisb.* 35(1/4):49-55; 1973/1974.

inical trials with amantadine hydrochloride (administered by nasal intubation) are reported in four patients with liver cirrhosis, hepatargia, and hepatic encephalopathy. Two patients (a 52-yr-old woman and a 51-yr-old man) both presenting with somnolence, asterixis, and EEG disturbances showed improvement of the clinical symptoms and EEG tracing after treatment (200 mg x 2 at 1- to 2-hr intervals). A 52-

yr-old man with hepatargia, somnolence, and mental confusion regained consciousness and had good mental orientation 12 hr after treatment (200 mg x 3 given at 4- and 12-hr intervals). No EEG tracings were recorded in this patient. A 65-yr-old comatose man with portacaval shunt, hepatargia, and low EEG frequencies showed no improvement from two doses of 200 mg and 300 mg, resp., given at 1.5-hr intervals; he died 12 hr after the administration of the first dose. These preliminary results are promising, and appear to be superior to those previously obtained with L-dopa.

2537 HEPATIC OCCLUSION VENOGRAPHY WITH A BALLOON CATHETER IN PATIENTS WITH END-TO-SIDE PORTACAVAL SHUNTS.

(Eng.) Novak, D.; Butzow, G. H.; Becker, K. (Univ. Hosp. Eppendorf, Hamburg, W. Germany). *Am. J. Roentgenol.* 127(6):949-953; 1976.

Eight patients with patent end-to-side portacaval shunts were examined by hepatic occlusion venography with the aid of a Swan-Ganz balloon catheter to study the collaterals found in the gallbladder after this type of shunt and to determine whether the bridging anastomoses developing between both sides of the intersected portal venous system after the procedure have hemodynamic or clinical significance in the postoperative course. Hepatic occlusion venography was used to avoid the disadvantages of the wedging procedure and to provide more reliable data. Seven patients had retrograde filling of portal vein branches and portosplanchnic collaterals. The only patient without collaterals had congenital periportal fibrosis. Tiny collaterals in the gallbladder region and large bridging anastomoses were found in four patients. Three patients had more than one type of collateral. The frequency and size of collateral formation suggest possible hemodynamic and clinical significance.

2538 SURFACE FEATURES OF CIRRHOTIC LIVER.

(Eng.) Nopanitaya, W.; Grisham, J. W.; Carson, J. L.; Dotson, M. M. (Sch. Medicine, Univ. North Carolina at Chapel Hill, Chapel Hill, NC 27514). *Virchows Arch.* [*Pathol. Anat.*] 372(2):97-108; 1976.

The surface features of single cells and of multicellular tissue units in rat livers made cirrhotic by concurrent treatment with phenobarbital and carbon tetrachloride were studied by scanning electron microscopy (SEM). Connective tissue septa consisted of a loose mesh-work of fibers in which fibroblasts were embedded. The arrangement and surface features of hepatocytes in cirrhotic nodules differed from those found in parenchyma of normal livers. Hepatocytes in cirrhotic nodules universally formed plates two cells thick. The portion of the hepatocyte surface covered by microvilli was greatly increased in cells from cirrhotic livers, and this was reflected in a corresponding reduction in the area occupied by the smooth-surfaced narrow intercellular space. Canaliculi between hepatocytes in cirrhotic livers were reduplicated and frequently branched. Hepatocyte surfaces covered by microplicae and flattened microvilli, typical of connective tissue-facing surfaces in normal livers, were greatly increased in cirrhotic livers, corresponding to the increase in connective tissue. At the points where hepatocytes directly contacted fibroblasts (and not fibers), their surfaces were smooth. Sinusoidal endothelial cells in cirrhotic livers contained only isolated, relatively sparse pores, and they lacked both sieve plates (pore complexes) and large fenestrations. This study demonstrates that hepatocyte surfaces and sinusoidal endothelial cells in cirrhotic livers differ considerably from those of normal liver. Most of the surface alterations probably reflect changes in cellular micro-environments or represent adaptive changes to altered physiologic conditions, such as blood and bile flow.

2539 DEMONSTRATION OF AN INTRACELLULAR COPPER-BINDING PROTEIN BY ORCEIN STAINING IN LONG-STANDING CHOLESTATIC LIVER DISEASES.

(Eng.) Salaspuro, M.; Sipponen, P. (Second Dept. Medicine, Univ. Helsinki, 00290 Helsinki 29, Finland). *Gut* 17(10):787-790; 1976.

The location and the association of orcein-positive material was compared histologically with the occurrence of copper in liver biopsies from eight patients with primary biliary cirrhosis, two with chronic active hepatitis of a cholestatic form, three with longstanding alcoholic liver cirrhosis, and one with extrahepatic biliary obstruction. In each case, dark brown cytoplasmic material was seen after staining of the tissue sections with Shikata's orcein method. In exactly the same cellular and subcellular locations as the orcein-positive material, and with morphologically equal granules, two different ordinary staining methods for copper (rubeanic acid and Mallory-Parker's hematoxylin) gave positive reactions Earlier histochemical findings have revealed the protein nature and high sulfhydryl content of the orcein positive material. Its close association with copper in liver sections suggests its copper-binding nature and indicates that a common copper-protein complex accumulates in the cytoplasm of liver cells during longstanding cholestasis in biliary diseases of various pathogenetic origins.

2540 X-RAY MICROANALYSIS OF COPPER ACCUMULATION IN LIVER SECONDARY BILIARY CIRRHOSIS.

(Eng.) Sipponen, P.; Hjelt, L.; Tornkvist, T.; Salaspuro, M. (Central Lab. Pathology, Univ. Helsinki, Haarmaninkatu, 3, SF-00290 Helsinki 29, Finland). *Arch. Pathol. Lab. Med.* 100(12):664-666; 1976.

X-ray microanalysis was carried out in liver biopsy sections from three patients with biliary cirrhosis to clarify its value in the detection of copper in histologic sections and to verify the suggested association of copper with sulfur in cholestatic liver diseases. Copper was demonstrable by x-ray microanalysis in one patient in whom biliary cirrhosis was caused by cholestatic liver disease associated with ulcerative colitis, but not in the two patients with primary biliary cirrhosis. The liver specimens of the patient with secondary biliary cirrhosis showed histochemically extreme amounts of copper in the liver cells. Copper could be seen by x-ray analysis as a few single accumulations if the sections were screened blindly. Iron was present in 1 of 10 copper accumulations studied consecutively. Zinc, nickel, cobalt, lead, manganese, chromium, vanadium, titanium, selenium, mercury, and gold were not detected. All copper accumulations contained sulfur, which was not found in measurable quantities at other sites. Calculations of relative quantities suggested that the molecular ratio of sulfur to copper in the accumulations was 2:1. The results support the suggestion that copper is bound to apoprotein through sulfhydryl groups within the hepatocytes of patients with cholestatic liver diseases and Wilson's disease.

2541 MORPHOLOGICAL TYPES OF HEPATOCELLULAR HYALIN IN INDIAN CHILDHOOD CIRRHOSIS: AN ULTRASTRUCTURAL STUDY.

(Eng.) Nayak, N. C.; Roy, S. (All India Inst. Medical Sciences, New Delhi, India). *Gut* 17(10):791-796; 1976.

he ultrastructure of morphological variants of intrahepatocytic hyalin in Indian childhood cirrhosis as investigated. The hyalin, morphologically identical to Mallory's alcoholic hyalin, was encountered in three different forms. The most frequent orm occurred as irregular masses of randomly riented interwoven fibrils admixed with electron ense granules. The next most common form, which ccurred almost as frequently as the first form, as composed of smudgy, homogeneous or finely gran- lar electron-dense material with no discernible ibrillary structure. The least common type of yalin appeared as closely packed bundles of fine ibrils arranged in parallel arrays. These fibrils ad a "finger-print" appearance. Fragmented ndoplasmic reticulum and ribosomes were frequent- y associated with hyalin, suggesting that these rganelles contribute to their formation.

542 25-HYDROXYLATION OF VITAMIN D IN PRIMARY BILIARY CIRRHOSIS.

(Eng.) Skinner, R. .; Sherlock, S.; Long, R. G.; Wills, M. R. (Royal ree Hosp., Pond St., London NW3 2QG, England). *ancet* 1(8014):720-721; 1977.

he ability of 39 patients with symptomatic primary iliary cirrhosis to 25-hydroxylate vitamin D was nvestigated by measuring serum 25-hydroxyvitamin D 25-OHD) before and after the i.m. injection of itamin D_2 (100,000 U). By the 12th day after the njection, basal serum 25-OHD had increased sig- ificantly in eight normal controls ($p<0.01$) and in even controls with osteomalacia ($p<0.01$), but not n seven previously untreated cirrhosis patients mean incremental values were 2.3 ± 1.7, 4.6 ± 2.7, nd 0.9 ± 2.4 ng/ml, resp.). Twenty-three of 25 irrhotic patients on regular vitamin D therapy monthly i.m. injections of 100,000 U for 6-72 nths) had normal serum 25-OHD values. The results ndicate that serum 25-OHD concentrations become rmal in primary biliary cirrhosis if adequate amounts of vitamin D are presented to the liver as substrate.

2543 EFFECT OF PORTAL-SYSTEMIC ANASTOMOSIS OF RENAL HAEMODYNAMICS IN CIRRHOSIS.

(Eng.) Ring-Larsen, H.; Hesse, B.; Stigsby, B. (Rigshospitalet, Univ. Hosp., Copenhagen, Denmark). *Gut* 17(11):856-860; 1976.

Central hemodynamics, portal pressure, and mean renal blood flow (RBF) were investigated immediately before and 2-7 months after portal-systemic shunt in 11 patients with advanced alcoholic or idiopathic cirrhosis and in a 28-yr-old female with presinusoidal portal hypertension of unknown etiology. Before the operation, the renal blood flow was significantly lower ($p<0.01$) in the patients (1.95 ml/g/min) than in controls (3.50 ml/g/min); after the portal-systemic shunt, it was unchanged (1.88 mg/g/min). Mean values of plasma volume (l), blood volume (l), cardiac output (l/min), stroke volume (ml), mean arterial blood pressure (mm Hg), intrasplenic pressure (mm Hg), and wedged hepatic venous pressure (mm Hg) before surgery were 3.93 ± 0.23, 5.68 ± 0.36, 5.56 ± 0.36, 72 ± 5, 87 ± 3, 29 ± 1, and 24.3 ± 2.0, resp. After the operation, the corresponding values were 4.01 ± 0.18, 5.68 ± 0.25, 6.76 ± 0.42, 92 ± 7, 82 ± 4, 17 ± 1, and 20.5 ± 2.0, resp. Since portal pressure decreased significantly after the portal-systemic shunt, a direct portal-renal, neural, or humoral reflex mechanism does not explain the subnormal renal blood flow values in cirrhosis, and since plasma volume was large and unchanged after the operation, a diminished circulating plasma volume is an unlikely explanation. It appears that previously postulated causes of renal hypoperfusion in cirrhosis need revision.

2544 PRIMARY BILIARY CIRRHOSIS WITH SCLERODERMA AND HYPOTHYROIDISM.

(Dut.) de Graaf, P.; van der Meer, J. W. M.; Schrijver, H. (Academisch Ziekenhuis, Leiden, Netherlands). *Tijdschr. Gastroenterol.* 18(3):151-160; 1975.

A woman with primary biliary cirrhosis was followed up for 21 yr. She was aged 50 yr at the onset of the disease. Hypothyroidism due to autoimmune thyroiditis was diagnosed 8 yr after the onset of the primary biliary cirrhosis. Systemic scleroderma was diagnosed during the 20th yr of follow-up. The patient developed cardiac insufficiency and died of progressive renal insufficiency. The triad of primary biliary cirrhosis, autoimmune thyroiditis, and systemic sclerosis is believed to belong to the idiopathic autoimmune diseases. Primary biliary cirrhosis and autoimmune thyroiditis are assumed to be due to cellular autoreactivity caused by yet unknown, but probably exogenous, factors. An immunological relation is likely to exist between the three diseases. It is not yet known whether this is due to the primary affection of the immune system or to the simultaneous lesion of several organs, or whether the primary lesion of one organ gives rise to the lesion of other organs by way of cross-antigenicity.

2545 PIGMENTED CORNEAL RINGS IN NON-WILSONIAN LIVER DISEASE. (Eng.) Fleming, C. R.; Dickson, E. R.; Wahner, H. W.; Hollenhorst, R. W.; McCall, J. T. (Mayo Clinic, Rochester, MN 55901). *Ann. Intern. Med.* 86(3):285-288; 1977.

The cases of four patients with non-Wilsonian liver disease who were found to have pigmented corneal rings are described. Eighty-one consecutive patients with primary biliary cirrhosis were examined with the slit-lamp in the course of their medical evaluation. Three patients were found to have corneal rings. A fourth patient presented with chronic active hepatitis in relapse 2 months after discontinuing prednisone therapy; cirrhosis was also present. Hepatic copper, serum copper, urinary copper, and serum ceruloplasmin concentrations were significantly elevated in all patients with primary biliary cirrhosis. Radiocopper (^{64}Cu or ^{67}Cu) plasma disappearance curves clearly differentiated patients with primary biliary cirrhosis from those with Wilson's disease. Three of the patients with primary biliary cirrhosis showed a secondary rise in radiocopper that presumably represented copper incorporation into ceruloplasmin. In one patient in whom ^{64}Cu in ceruloplasmin was studied specifically, incorporation was normal. An unexplained finding in the patient with chronic aggressive hepatitis was a very high serum iron level of 313 μg/dl (89% saturation) and desferrioxamine chelatable iron of 1,248 μg. However, her hepatic and bone marrow iron stores were not excessive. None of the four patients had a family history of hepatic, neurologic, or psychologic disease, and none showed neurologic or psychiatric disorders. Pigmented corneal rings in the presence of chronic liver disease without neurologic disease can be seen in Wilson's disease, primary biliary cirrhosis, and chronic active liver disease. These diseases can be differentiated with the help of history, immunologic and biochemical variables, chemical tests for copper metabolism, and radiocopper kinetics.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

66 FACTORS INTERFERRING [sic] WITH THE OPACIFICATION OF A NORMAL GALLBLADDER. (Eng.) jahed, Z. (525 E. 68 St., New York, NY 10021). *strointest. Radiol.* 1(2):183-185; 1976.

trinsic factors that will interfere with the satisctory opacification of a normal gallbladder are esented. These include: faulty instructions to e patient, excessive diarrhea and vomiting (likely occur with larger doses than recommended), small testinal resection and gastrointestinal anastomoses, sease of the small intestine (especially malsorptive diseases), liver disease anastomoses or stulous formation between the biliary system and e gastrointestinal tract, inadequate opacification me, cholestasis due to a low-fat diet, and pancreatic diseases. Some of these factors are inequent, but as a group they become significant. less they are ruled out, they may lead to the roneous diagnosis of nonopacification because disease.

2567 DISEASE OF THE GALLBLADDER IN PATIENTS WITH NORMAL CHOLECYSTOGRAMS. (Eng.) Andersson, A.; Bergdahl, L. (Central Hosp., S-291 85 Kristianstad, Sweden). *Am. J. Surg.* 132(3):322-324; 1976.

Eight cases of gallbladder disease in which the cholecystogram was false-negative are described; one illustrative case report is presented. The survey consisted of 5,000 patients who had been subjected to cholecystectomy between July 1962 and May 1974. Among the eight patients with false-negative cholecystograms, seven were women. Six patients had been examined up to nine times with cholecystography or cholegraphy. The symptoms were typical of gallbladder disease and moderately severe. Four patients had gallbladder stones, while the remaining four had only cholesterolosis of the gallbladder. Two patients had had recurrent attacks of pancreatitis. The patient whose case report is presented was a 73-yr-old man whose history included duodenal ulcer and biliary colic attacks. The patient presented with acute pancreatitis with an abnormally elevated serum amylase level. Cholecystography was normal and continued to be normal on six subsequent occasions, when the patient was hospitalized for recurrent attacks of pancreatitis and symptoms suggestive of gallbladder disease. Laparotomy 13 yr later revealed postinflammatory changes around the gallbladder and, adjacent to the gallbladder bed, a liver abscess, which was drained. The gallbladder mucosa contained several cholesterol polyps that had not been shed. Operative cholangiography showed that the common bile duct was 10 mm wide and contained no stones. The patient remains asymptomatic 9 months after cholecystectomy.

2568 CHIBA PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. A VALUABLE METHOD FOR VISUALIZING THE NONDILATED BILIARY TRACT.

(Eng.) Tabrisky, J.; Lindstrom, R. L.; Hanelin, L. G.; Pfisterer, W. F. (Harbor General Hosp., 1000 West Carson St., Torrance, CA 90509). *Am. J. Roentgenol.* 126(4):755-760; 1976.

Percutaneous transhepatic cholangiography (PTC) is the procedure of choice for diagnosis of lesions that obstruct the biliary tract. Japanese investigators have developed a long, thin sheathless (Chiba) needle to replace the large, sheathed needle originally used in this procedure. The Chiba needle reduces the risk of major complications, but more importantly, it allows the visualization of normal (nondilated) or small bile ducts. As examples of the value of Chiba PTC, four remarkable case histories are presented in which Chiba PTC resolved the lesion where other diagnostic procedures failed. The success rate for Chiba PTC, especially in cases with small, nondilated ducts, is very high, with extremely few major complications (1 in 120 cases). The major advantages of Chiba PTC are technological ease, small needle size, and ability to cannulate small ducts. This procedure can save the patient from needless exploratory surgery. The authors conclude that the technique is a valuable primary procedure or alternative to endoscopic retrograde cholangiography.

2569 A HISTOPATHOLOGICAL STUDY OF THE REMNANT OF EXTRAHEPATIC BILE DUCT IN SO-CALLED UNCORRECTABLE BILIARY ATRESIA.

(Eng.) Miyano, T.; Suruga, K.; Tsuchiya, H.; Suda, K. (Juntendo Univ. Sch. Medicine, 3-1-3 Hongo, Bunkyo-ku, Tokyo, Japan). *J. Pediatr. Surg.* 12(1):19-25; 1977.

Histopathological studies of remnants of extrahepatic bile duct and wedge liver biopsies were performed in 40 cases of so-called uncorrectable biliary atresia treated by hepatic portoenterostomy. Histological specimens were classified into three types: type I, the inside diameter of the bile duct was more than 100 μm, and there was not much inflammatory change in surrounding tissue (type Ia, ductal inside diameter greater than 300 μm; type Ib, ductal inside diameter less than 300 μm); type II, the inside diameter of the bile duct or ductuli was less than 100 μm, with small round cell infiltration and vessel proliferation in surrounding tissue; and type III, fibrosis without any ductal structure. In terms of correlation between the histological findings and the region of the remnant of the extrahepatic bile duct, the incidences of type I specimens in the areas of the porta hepatis, hepatic duct, choledochus, and gallbladder were 25% (2 type Ia and 8 type Ib), 24% (0 type Ia and 8 type Ib), 34% (7 type Ia and 4 type Ib), and 37% (33 type Ia and 4 type Ib), resp. The corresponding incidences for type II specimens were 58% (23 cases), 26% (9 cases), 13% (4 cases), and 2.5% (1 case), resp. The corresponding incidences of type III specimens were 17% (7 cases), 50% (17 cases), 53% (17 cases), and 2.5% (1 case), resp. The older the patient, the smaller the size of the duct at the porta hepatis and the more advanced hepatic fibrosis. Patients aged 2.5 months showed a 57% incidence of type I specimens and a 0% incidence of type III specimens, whereas patients between 3 and 4 months of age showed a 14% incidence of type I specimens and a 29% incidence of type III specimens. Type I specimens at the porta hepatis were associated with a 40% incidence of type I fibrosis and a 30% incidence of type III fibrosis, whereas type III specimens were associated with a 0% incidence of type I fibrosis and a 57% incidence of type III fibrosis. It is recommended that the operation be performed at as early an age as possible.

2570 RAPID ROENTGENOLOGIC DIAGNOSIS OF ACUTE CHOLECYSTITIS.

(Eng.) Danley, R. B.; Love, L.; Pickleman, J. R. (Loyola Univ. Medical Center, Maywood, IL). *Surg. Gynecol. Obstet.* 143(4): 602-604; 1976.

A new rapid method of roentgenographic visualization of the acutely inflamed gallbladder is described; this technique, infusion tomography, was performed 146 times, and the results are presented. With the patient in the prone position and using a low kV peak technique, linear tomographic scout films are taken. Sixty percent meglumine diatrizoate (2.2 ml/kg) mixed with 5% glucose and water is rapidly infused i.v. Immediately after the infusion, tomographic sections of the anterior third of the abdomen are taken at 1-cm levels. Of the 146 patients who underwent this procedure, 67 underwent cholecystectomy, 51 having had an abnormal infusion tomogram and 16, normal linear tomograms. Of the 27 patients with histologically proven acute or chronic cholecystitis with superimposed acute cholecystitis, 26 had an abnormal infusion tomogram. In patients with subacute or chronic cholecystitis, the correct positive result rate was 64%. There were no false-positive results. In view of the high false-negativ rate in instances of subacute and chronic cholecystitis, it is advised that all normal roentgenograms be followed by p.o. cholecystography.

2571 THE EFFECT OF HEPATIC BILE ON RETAINED COMMON DUCT STONES.

(Eng.) Thurston, O. G.; McDougall, R. M. (Dept. Surgery, Univ. Alberta, Edmonton, Alberta, Canada). *Surg. Gynecol. Obstet.* 143(4):625-627; 1976.

The natural history of 91 patients with common duct stones presenting clinically after cholecystectomy was examined, and data indicating the effect of hepatic bile on common duct stones after cholecystectomy were obtained. Nine of the 91 patients were judged to have primary common duct stones, and the remaining 82 patients had secondary stones, which were multiple in 41 instances. In contrast to the theoretic incidence curve for patients with choledocholithiasis presenting after cholecystectomy, the actual plot for the 91 patients showed a bimodal distribution, with an early peak in the first year, followed by a second peak at 3 yr after cholecystectomy. Three years after cholecystectomy, there was a gradual diminution in the number of patients who presented with stones each year up to 54 yr after cholecystectomy. It is concluded that retained common duct stones increase in size with the passage of time, eventually becoming large enough to be symptomatic. In these patients, bile is thought to remain supersaturated with cholesterol after cholecystectomy.

2572 ABNORMALITIES IN GALLBLADDER MORPHOLOGY AND FUNCTION IN PATIENTS WITH CHOLELITHIASIS. (Eng.) Nahrwold, D. L.; Rose, R. C.; Ward, S. P. (Milton S. Hershey Medical Center, Hershey, PA 17033). *Ann. Surg.* 184(4):415-421; 1976.

Relations between clinical manifestations, histologic findings, and gallbladder absorptive capability were studied in 37 symptomatic cholelithiasis patients who underwent cholecystectomy. Clinical scoring was based on symptoms within 7 days of surgery, degree of abdominal tenderness, nonvisualization on cholecystogram, left shift differential count, previous acute cholecystitis, and fever or elevated WBC during prior attack. Histologic scoring (light microscopy) was based on fibrosis, mucosal diverticula (Rokitansky-Aschoff sinuses), cholesterolosis, muscle thickening, and inflammatory cell infiltrate; the presence of plasma cells and eosinophils was assessed separately. Short-circuit current measurements, which reflect gallbladder sodium absorption, were used to assess absorptive function. Patients with clinical scores of 0-3, indicative of minimal clinical signs and symptoms, had a mean histologic score of 6.5 ± 0.6 and a mean short-circuit current of 64 ± 6 μamp, whereas patients with clinical scores of 4-8 had a mean histological score of 11.6 ± 1.3 and a mean short-circuit current of 39 ± 9 μamp. The differences between the two histological and the two short-circuit current means were significant ($p<0.01$ and $p<0.05$, resp.). A significant linear relation ($r=0.78$) existed between short-circuit current values and histologic scores. The linear relations between clinical scores and histologic scores ($r=0.64$) and short-circuit current values and clinical scores ($r=0.58$) were less significant. The mean short-circuit (64 ± 6 μamp) for gallbladders that visualized on p.o. cholecystography was significantly higher ($p<0.02$) than the mean value (32 ± 11 μamp) for gallbladders that did not visualize, but there was considerable overlap between the two groups. Visualization on p.o. cholecystography does not appear to be a reliable measure of gallbladder absorptive capacity.

2573 INCREASED INCIDENCE OF CHOLELITHIASIS IN LIVER CIRRHOSIS. ANALYSIS OF THE CAUSES OF INCREASED FREQUENCY. (Spa.) Viveros, J. G.; Villalobos, J. J.; Wolpert, E. (Departamento de Gastroenterologia, Instituto Nacional de la Nutricion San Fernando y Viaducto, Tlalpan, Mexico 22, D.F.). *Rev. Invest. Clin.* 27(4):269-273; 1975.

The files of 10,000 patients treated at the Instituto Nacional de la Nutricion during 1970-1973 were reviewed for cases of liver cirrhosis (339) or cholelithiasis (601) and were statistically analyzed for lithiasis. Cirrhosis was determined by clinical examination and liver function tests, with confirmation by biopsy or autopsy in most cases. Cholelithiasis was diagnosed by radiology (negative oral cholecystogram: inconclusive). There were 41 cases of cholelithiasis among 339 cirrhosis patients and only 601 cases of cholelithiasis among 9,661 noncirrhotics. Cholelithiasis occurred in 442 men and 118 women with cirrhosis. In noncirrhotics, cholelithiasis was found in 19 men and 22 women. Chronic hemolysis seemingly explains increased pigmented gallstones in liver cirrhosis.

2574 CHOLELITHIASIS IN PERSONS UNDER 25 YEARS OLD: CLINICOPATHOLOGIC REVIEW OF 96 CASES. (Eng.) Goodman, D. B. (Naval Regional Medical Center, 7500 E. Carson St., Long Beach, CA 90801). *JAMA* 236(15):1731-1732; 1976.

The clinicopathologic features of cholelithiasis in 96 surgically treated patients between 7 and 25 yr of age were studied. Although females predominated in a ratio of 4:1, the sex incidence was equal when nulliparous females were compared with males. Early in the course of the disease, the symptoms were usually nonspecific. Only 28 patients experienced acute upper abdominal pain at some time in their course, and 4 patients noted jaundice in addition to abdominal pain. There was a delay in proper diagnosis in 26% of the patients; the total duration of symptoms to diagnosis was up to 1 month in 9 patients, 2-12 months in 56 patients, 1-5 yr in 24 patients, and over 10 yr in 1 patient. Only two patients had an underlying blood dyscrasia. The most reliable diagnostic test was p.o. cholecystography. All patients underwent cholecystectomy. The incidence of choledocholithiasis was 4.1%. The data indicate that cholelithiasis occurs frequently in patients younger than 25 yr in the absence of hemolytic disease or history of pregnancy.

2575 PIGMENT GALLSTONES. (Eng.) Soloway, R. D.; Trotman, B. W.; Ostrow, J. D. (Hosp. Univ. Pennsylvania, 3600 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 72(1):167-182; 1977.

The composition of pigment gallstones, experimental gallstone production, and the features that distinguish patients with pigment stones from those with cholesterol stones are reviewed, and the treatment and etiology are discussed. Pigment gallstones are defined as any dark brown-to-black stone, consisting of calcium salts of bilirubin, phosphate, carbonate and other anions; it can be separated into carbonate- and noncarbonate-containing groups. Pigment stones predominate in the rural Orient, in cirrhosis, and in elderly patients in the U.S. undergoing cholecystectomy. Clinical associations include bile duct obstruction, stasis, and possibly hemolysis. Fifty percent of pigment stones are radiopaque and account for two-thirds of all opaque stones. The concentrations of bile salts, phospholipids, cholesterol, and total bilirubin in bile are similar to normal levels, but the concentration of unconjugated bilirubin is increased in the bile of some patients. Increased unconjugated bilirubin in bile may be caused by increased hydrolysis of excreted conjugated bilirubin. Unconjugated bilirubin is solubilized by bile salts, but the interaction is primarily nonmicellar. Ionized calcium and pH are important determinants of solubility. Sulfated glycoproteins, excreted in increased amounts in patients with cholelithiasis, may be the site of pigment stone precipitation because these compounds bind calcium salts tightly. *Escherichia coli* is frequently cultured from pigment stones in Japan, but not in the U.S.; thus, bacterial β-glucuronidase may be important in stone formation in Japan, but probably not in the West. Stasis leads to increased calcium secretion and to increases in the concentration of sparingly soluble compounds that may then precipitate. Incomplete emptying of the gallbladder may result in the same concentration process. Unsaturated fats and chronic vagal stimulation cause pigment stone formation in animals. Surgery is presently the only treatment for pigment lithiasis.

2576 THE WORLD DISTRIBUTION OF GALLSTONES.

(Eng.) Brett, M.; Barker, D. J. P. (Southampton General Hosp., Southampton SO9 4XY, England). *Int. J. Epidemiol.* 5(4):335-341; 1976.

A summary of all available published data since 1890 on the world distribution of gallstones, as recorded from autopsy studies, is presented. From 1940 onwards, the mean prevalence recorded in European countries was 18.5%, with the lowest value being recorded in Dublin, Ireland (5%) and the highest in Malmo, Sweden (38%). Before 1940, the mean prevalence was 10.5%, with the lowest value being found in London in 1911 (3%) and the highest in Vienna in 1927 (32%). The male:female ratio for prevalence is about 1:2. Mixed cholesterol stones were found most often. In America, the mean prevalence in whites and negroes from 1940 onwards were 9 and 24%, resp. The mean prevalence for pre-1940 surveys was 9.4%, with the lowest value being recorded in Chicago in 1918 (3%) and the highest in Rochester (22%). High prevalences of 24, 30, and 32% were recorded among American Indians during studies performed in the 1960's. High values of 15, 21, and 35% were also found in recent surveys in Santiago, Chile. The overall male:female ratio in North America whites is about 1:2 and in negroes 1:3. Prevalence among whites is approximately twice that among negroes. Stones in Americans are mostly of the mixed cholesterol type. Low prevalences have been recorded in Africa, other than South Africa (less than 1%), and in Asia (7% for Singapore), where the majority of stones are of the pigmented type. In South Africa, the prevalence among whites ranges from 14 to 17% and in the Bantu, from 2-5%. Females are affected about twice as often as males. Whites have mainly mixed cholesterol stones, while the majority of stones in the Bantu are pigmented. Data for Brisbane, Australia in 1971 showed a prevalence of 31%; earlier studies in Adelaide and Melbourne revealed lower values of 11, 13, and 15%. The male:female ratio was about 1:2. Additional studies, especially in Asia, Russia, the Middle Eastern and Mediterranean countries, and South America, are needed to help clarify the etiology of gallstones.

2577 SULPHATED AND UNSULPHATED BILE ACID IN SERUM, BILE, AND URINE OF PATIENTS WITH CHOLESTASIS.

(Eng.) Van Berge Henegouwen, G. P.; Brandt, K. H.; Eyssen, H.; Parmentier, G. (St. Radboud Hosp., Nijmegen, Netherlands). *Gut* 17(11):861-869; 1976.

To gain insight into the changes occurring in bile acid metabolism in cholestasis, samples of serum, bile, and urine were collected simultaneously from 32 patients with cholestasis of varying etiology and from 18 patients with cirrhosis; their bile acid composition was determined by gas/liquid chromatography and mass spectrometry. In cholestasis, the patterns in all three body fluids differed consistently and strikingly. In serum, cholic acid was the major bile acid, and most bile acids (>93%) were unsulphated, whereas, in urine, chenodeoxycholi acid was the major bile acid, and the majority of bi acids (>60%) were sulphated. Secondary bile acids w virtually absent in bile, serum, and urine. The tot amount of bile acids excreted for 24 hr correlated highly with the concentration of serum bile acids; patients with complete obstruction, urinary excretio averaged 71.6 mg/24 hr. In cirrhotic patients, serum bile acids were less raised, and chenodeoxycholic acid was the predominant acid. In healthy controls, serum bile acids were consistently richer in chenodeoxycholic acid than biliary bile acids, a no bile acids were present in urine. No unusual monohydroxy bile acids were present in patients wit primary biliary cirrhosis, but, in several patients, there was a considerable amount of hyocholic acid present in the urinary bile acids. The analyses of individual bile acids in serum and urine did not appear to provide helpful information in the differential diagnosis of cholestasis. Thus, in cholestasis, conjugation of chenodeoxycholic acid with sulphate becomes a major biochemical pathway, urine becomes a major route of bile acid excretion, and abnormal bile acids are formed.

2578 JAUNDICE FROM IMPACTED SEDIMENT IN A T TUBE: RECOGNITION AND TREATMENT.

(Eng.) Jelaso, D. V.; Hirschfield, J. S. (Clearwater Commu nity Hosp., Clearwater, FL 33516). *Am. J. Roentge ol.* 127(3):413-415; 1976.

he case of a 66-yr-old man in whom encrustation of
ile sediment in the proximal limb of an indwelling
-tube occluded the lumen, causing jaundice, is pre-
ented. A T-tube had been inserted across the nar-
owed segment of common hepatic duct into the left
epatic duct when adenocarcinoma of the proximal
ucts was discovered. The patient did well for 5
onths, after which jaundice occurred. The occlusion
as detected by a T-tube cholangiogram, and attempts
o disimpact the bile sediment plug by irrigation
ith saline and the use of standard and moving core
uide wires were unsuccessful. A 1.65-mm Bilbao-
otter hypotonic duodenography torque cable was suc-
essfully advanced across the occluded proximal limb
f the T-tube. Repeated saline irrigations and cable
nsertions restored patency. Torque cable disimpac-
ion of the plugged T-tube was required on several
ccasions up until the patient's death 24 months af-
er the initial admission. The insertion of a torque
able under fluoroscopic control can successfully
isimpact this type of occlusion, restoring patency
nd relieving the jaundice.

579 ENDOTOXIN, BILE SALTS AND RENAL FUNCTION IN OBSTRUCTIVE JAUNDICE. (Eng.) Bailey,
. E. (King's Coll. Hosp., London, England). *Br.*
. *Surg.* 63(10):774-778; 1976.

ndotoxemia and renal function were studied in 24
atients with obstructive jaundice who underwent
urgery for cancers of the bile duct or pancreas,
allstones, bile duct stricture, stone in the
ommon bile duct, cancer with secondary deposits,
ancer of the pancreas plus gallstones, or hepatoma
nvading the bile duct. Endotoxin in the portal
lood was seen at surgery in 16/24 jaundiced patients,
nd 13 of these had endotoxin in their peripheral
lood. Only 3 patients had proven sites of infection,
hich possibly accounted for the peripheral endotox-
mia; thus, 10 patients almost certainly developed
ortal and peripheral endotoxemia from their own
astrointestinal organisms. Only untreated patients
ith a serum bilirubin of 8.5 mg/100 ml or more had
ndotoxin in the portal blood. The mean preoperative
reatine clearance in nonendotoxin patients was
2.72 ml/min and was not significantly different
rom a preoperative value of 70.39 ml/min for endo-
oxin-positive patients. The mean postoperative
reatine clearance values in nonendotoxin and
ndotoxin patients were 93.27 ml/min and 39.69 ml/
in, resp. ($p<0.0025$). No portal or peripheral
ndotoxemia and no significant fall in postoperative
reatine clearance were observed in 16 nonjaundiced
ontrol patients. Experiments with Wistar rats,
hich underwent bile duct ligation and 12 days later
eceived sodium taurocholate (8 mg/100 g t.i.d.
2 days, p.o.) and then *Escherichia coli* endotoxin
5 mg/100 g, p.o.) and lead acetate (5 mg/100 g,
.v.) 3 hr later, indicated that absorption of
ndotoxin in the intestinal tract can be prevented
y bile salt administration.

580 ROUX-EN-Y BILIODIGESTIVE ANASTOMOSIS. INDICATIONS AND LONG-TERM CLINICAL AND
OCHEMICAL RESULTS. (Dut.) Verbeke, W.; Vanmaele,
.; Detournay, G.; Kerremans, R.; Beckers, J.; de
Groote, J. (Academisch Ziekenhuis Leuven, Louvain, Belgium). *Tijdschr. Gastroenterol.* 18(3):133-150; 1975.

Results obtained with a Roux-en-Y biliodigestive anastomosis in 26 patients with obstructive jaundice (14 patients) and intermittent cholangitis (12 patients) are presented. The postoperative mortality amounted to 1/26 (3.8%). Eighteen patients (69.2%) developed postoperative complications (wound infection, eventration, fistula, pulmonary and cardiac complications, phlebitis, septicemia, subhepatic abscess, fistula with nonfunctioning anastomosis, and choleperitoneum). Five patients (19.2%) developed stricture of the anastomosis, and duodenohemipancreatectomy was necessary in another. Twenty-two patients were followed up for up to 17 yr. The long-term subjective results were very good in 12 patients (55%), good in 2 (9%), and poor in 8 (36%). All patients in the latter group had abnormal liver function tests (bilirubin, BSP, alkaline phosphatase, and thymol and necrosis tests). Four patients developed liver cirrhosis; two of them died after an evolution of 5 yr. Roux-en-Y anastomosis is indicated principally for stenosis of the bile duct following biliodigestive anastomosis and for traumatic lesions of the bile duct leading to postoperative fistula of localized stricture.

2581 ENDOSCOPIC RETROGRADE CHOLANGIODILATATION: A PRELIMINARY REPORT. (Eng.) Lee, T. G.; Katon, R.; Freeny, P. C.; Henderson, S. C.; Bilbao, M. K. (Univ. Oregon Health Sciences Center, 3181 SW Sam Jackson Park Road, Portland, OR 97201). *Gastrointest. Endosc.* 23(3):171-172; 1977.

The case report of a patient in whom endoscopy was used to dilate a common bile duct stricture is presented. The patient, a 65-yr-old woman, had undergone choledochoduodenostomy 23 yr earlier. Endoscopic retrograde cholangiography demonstrated a tight stricture of the common bile duct. Using a 5 French Fogarty catheter outrigged to a front-viewing Olympus GIF-D panendoscope, the common bile duct was cannulated, and the inflated balloon was pulled through the stricture several times. The patient experienced no discomfort or complication. Therapeutic applications of the fiberoptic endoscope should be further investigated.

GENERAL

2588 THE EFFECTS OF TWO DIETARY FIBER SUPPLEMENTS ON GASTROINTESTINAL TRANSIT, STOOL WEIGHT AND FREQUENCY, AND BACTERIAL FLORA, AND FECAL BILE ACIDS IN NORMAL SUBJECTS. (Eng.) Baird, I. M.; Walters, R. L.; Davies, P. S.; Hill, M. J.; Drasar, B. S.; Southgate, D. A. T. (West Middlesex Hosp., Isleworth, Middlesex, England). *Metabolism* 26(2):117-128; 1977.

The effects of dietary supplements of sugar cane fiber (bagasse) on stool weight, solids, and water content were studied in 20 normal women over a 9-month period; a second inpatient study was done with bran supplements in four subjects. The addition of 10.5 g of bagasse containing 5.1 g of crude fiber to a normal diet containing 3.7 g of crude dietary fiber daily raised the mean fecal weight from 88.3 ± 6.4 g to 139.7 ± 10.2 g/day ($p<0.005$). There was also a significant rise in fecal solids and fecal water, although the percentage of water in the stools remained unchanged. Bagasse supplements accelerated gastrointestinal transit when measured by the carmine marker technique. Radiopaque "shapes" showed a trend toward more rapid transit with bagasse supplements. Daily supplements of 39 g of wheat bran or 10.5 g of bagasse increased the total daily excretion of fecal bacteria, but the amount of bacteria excreted per gram of feces did not change. The composition of the bacterial flora showed no change. There was increased excretion of fecal acid sterols on the bagasse supplement, but this did not occur with bran. No changes attributable to fiber supplements occurred in the plasma triglycerides or cholesterol. Future work may define specific dietary fiber supplements for different therapeutic purposes; one fiber may be used as a bulk expander in diverticular disease and another as a hypocholesteremic fiber.

2589 DEATH IN ACUTE UPPER GASTROINTESTINAL BLEEDING: CAN ENDOSCOPY REDUCE MORTALITY? (Eng.) Logan, R. F. A.; Finlayson, N. D. C. (Royal Infirmary, Edinburgh EH3 9YW, Scotland). *Lancet* 1(7970):1173-1175; 1976.

To determine the value of an emergency endoscopy service in reducing the mortality rate from acute upper gastrointestinal bleeding, the records of 64 patients who had died during a 24-month period between 1972 and 1974 were examined. Acute gastrointestinal bleeding had resulted in hospitalization in 43 patients or had become a major clinical problem during hospitalization in 21 others. Forty-six patients were over 60 yr of age. Recurrent or continuous bleeding occurred in 24 cases; after the exclusion of 9 deaths from sudden exsanguination and of 11 deaths from bleeding varices with subsequent hepatic failure, only 4 patients died from recurrent bleeding. Other causes of death were postoperative complications (20) and other seve concomitant disease (20). These results suggest that improved diagnostic techniques, such as endosco may not significantly reduce the mortality from acut upper gastrointestinal bleeding.

2590 THE PATIENT WITH ACUTE DIARRHEA: AN ALGORITHM FOR DIAGNOSIS. (Eng.) Satterwhite, T. K.; DuPont, H. L. (Univ. Texas Health Science Center, 6400 W. Cullen St., Houston, TX 77030). *JA* 236(23):2662-2664; 1976.

An algorithm for diagnosis in patients with acute diarrhea is presented. Patients who should be hospitalized include the very young or elderly with severe diarrhea and patients of any age with diarrhea and pronounced systemic toxemia, hyperpyrexia, or dehydration. When drug-associated diarrhea is suspected, the therapy should be discontinued and proctoscopy performed to see if a pseudomembran is present. Antimicrobial agents such as clindamyc and lincomycin hydrochloride monohydrate, in particular, may cause diarrhea. In food-borne illness, staphylococcal toxin-mediated illness is to be suspected if the symptoms occur 2-4 hr after ingestion and if vomiting is prevalent. If the onset is 12-1 hr after ingestion, *Clostridium perfringens* is the likely agent. If fecal WBC are present, infections by *Salmonella*, *Shigella*, *Yersinia*, and *Escherichia coli* are likely, producing diarrhea by causing colonic mucosal inflammation. If diarrhea lasts longer than 1 week, the stools should be examined for prot zoa. The common parasitic organisms include *Giardi lamblia*, *Entameba histolytica*, and occasionally, *Dientameba fragilis*. If the illness does not abate

thin 2 weeks, small bowel intubation with aspira-
on and biopsy may show *G. lamblia*.

91 CHOLESTYRAMINE IN TREATMENT OF POST-
VAGOTOMY DIARRHOEA--DOUBLE-BLIND CONTROLLED
IAL. (Eng.) Allan, J. G.; Russell, R. I. (Royal
firmary, Glasgow G4 OSF, Scotland). *Br. Med. J.*
6062):674-676; 1977.

e effectiveness of cholestyramine in treating
vere continuous postvagotomy diarrhea was eval-
ted in a double-blind, controlled trial, which
cluded 16 patients who had this symptom for at
ast 2 yr. Eight patients received 4 g of choles-
ramine three times daily, while the remaining pa-
ents received a placebo. Clinical assessments
the daily stool frequency, consistency, and
gree of urgency were made at 4 and 8 weeks of
eatment, and the patient's and clinician's
sessments of improvement were noted at these
mes. Although the numbers were too small for
atistical analysis, the patients treated with
olestyramine showed considerable improvement
er those given placebo. In the former group, all
t one patient believed that the drug had im-
oved the symptoms, and three thought that it had
mpletely relieved them; the assessments by
e doctor and patient correlated in all but one
tient who, nevertheless, had a reduction in stool
equency. Among the patients treated with place-
, only two patients thought that their symptoms
d improved, due to a decrease in urgency. Six
tients on cholestyramine and two patients on
acebo noted an improvement in stool consistency.
de-effects were noted in five patients on choles-
ramine (vomiting, 1; nausea, 3; lethargy, 1; heart-
rn, 1; abdominal cramp, 2), but none were serious.
t appears that cholestyramine may be of value in
e management of some patients with severe
ntinuous postvagotomy diarrhea who are unrespon-
ive to other forms of treatment.

592 NECROTIZING ENTEROCOLITIS AND HYPERVISCO-
SITY IN THE NEWBORN INFANT. (Eng.)
akanson, D. O.; Oh, W. (Women and Infants Hosp.
hode Island, 50 Maude St., Providence, RI 02908).
. *Pediatr.* 90(3):458-461; 1977.

1-yr prospective survey was undertaken to deter-
ine the incidence of whole blood hyperviscosity
HV) and necrotizing enterocolitis (NEC) in small-
or-gestational age (SGA) infants. Among 79 SGA
nfants, 14 had a blood viscosity that was 2 stand-
rd deviations or greater than the normal values;
hey were considered to have HV. Of these 14 in-
ants, 5 developed NEC, whereas only 1 of 65 SGA in-
ants with normal blood viscosity had NEC ($p<0.005$).
comparison of the clinical features of the five
V infants with NEC and the features of cases re-
orted in the literature showed that the latter
nfants had longer gestational periods (36-40 weeks
ersus $\leq$ 34 weeks) and higher birth weights (1,370-
,430 g versus $\leq$ 1,500 g). In contrast to those
eported in the literature, these infants were free
f clinical evidence of asphyxia or respiratory distress. The authors propose that HV may be another factor leading to ischemia in the gastrointestinal tract, with subsequent development of NEC.

2593 IMPORTANCE OF THE COLON IN ENTERIC HYPEROXALURIA. (Eng.) Dobbins, J. W.; Binder, H. J. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *N. Engl. J. Med.* 296(6):298-301; 1977.

To investigate the role of the colon in increased oxalate absorption, urinary oxalate and fecal fat excretion were measured in 26 patients with gastrointestinal diseases. Eight patients with intact colons and steatorrhea (caused by Crohn's disease, chronic pancreatitis, jejunoileal bypass, or extrahepatic biliary obstruction) had hyperoxaluria (>45 mg/24 hr). None of five patients with ileostomies and steatorrhea secondary to ileal resection had hyperoxaluria. ^{14}C-oxalate absorption was increased in three patients with steatorrhea and intact colons (>35% excretion), but not in three patients with steatorrhea and ileostomy (<10% excretion). The results indicate that the colon is the site of increased oxalate absorption in enteric hyperoxaluria and is required for this process. The lack of a direct relation between fecal fat excretion and urinary oxalate excretion in the patients with hyperoxaluria and steatorrhea suggests that steatorrhea is not the only determinant in the pathogenesis of hyperoxaluria.

2594 THE VIPoma: FURTHER CONFIRMATION OF VIP AS THE HORMONAL AGENT IN THE WDHA SYNDROME. (Eng.) Shield, C. F., III; Haff, R. C. (Wilford Hall U.S. Air Force Medical Center, Lackland Air Force Base, TX 78236). *Am. J. Surg.* 132(6):784-786; 1976.

The case of a patient with the watery diarrhea hypokalemia achlorhydria (WDHA) syndrome, in whom serum and tumor assays for gastrin, vasoactive intestinal peptide (VIP), and prostaglandins E and F were carried out, is presented. A 39-yr-old man presented with a 1-yr history of recurrent watery diarrhea and proximal muscle weakness. Gastric analysis demonstrated achlorhydria. Despite massive i.v. fluid and electrolyte replacements, at times requiring up to 340 mEq KCl/day, 15-18 l of i.v. fluid, and bowel rest, the diarrhea persisted. The patient also experienced an episode of hypokalemic uremia. At exploratory celiotomy, a 20-cm tumor was found in the tail of the pancreas. The patient underwent distal hemipancreatectomy with incontinuity splenectomy, midtransverse colectomy, and colocolostomy. In the immediate postoperative period, the symptoms resolved, and the patient has been completely asymptomatic with normal serum electrolytes during a 2-yr follow-up period. The pre- and postoperative serum VIP levels were 5,000 and 100 pg/ml, resp.; the respective values for gastrin and prostaglandins E and F were 80 and 76 pg/ml, 525 and 300 pg/ml, and 369 and 100 pg/ml. In the tumor, the VIP, prostaglandin E, and prostaglandin F levels were 1,000 pg/ml, 1.6 ng/g, and 0.5 ng/g, resp. A review of the literature concerning gastrin, secretin, glucagon, enteroglucagon, gastric inhibitory peptide (GIP), VIP, and prostaglandins as possible etiologic agents for the WDHA syndrome leads to several hypotheses. The reports of secretin, glucagon, and GIP as the etiologic agents could be secondary to contamination of these polypeptide preparations with VIP. Another possibility is antibody cross-reactivity due to the similar amino acid sequence of this group of peptides. Standardization of the VIP assay should result in increased recognition of this disease prior to the fulminant clinical presentation.

2595 A SURVEY OF OPPORTUNITIES AND NEEDS IN RESEARCH ON DIGESTIVE DISEASES. WORK GROUP XI. PSYCHOSOCIAL FORCES. (Eng.) Wolf, S.; Bonfils, S.; Brooks, F.; Groen, J. J.; Smith, G.; Weiner, H.; *et al.* (No affiliation given). *Gastroenterology* 69(5):1161-1164; 1975.

GENERAL

Parasitology

59 ELECTRON MICROSCOPY IN THE DIAGNOSIS OF GIARDIASIS. (Eng.) Klima, M.; Gyorkey,
; Min, K. W.; Gyorkey, F. (Veterans Admin. Hosp.,
)2 Holcombe Blvd., Houston, TX 77211). *Arch.*
thol. Lab. Med. 101(3):133-135; 1977.

ospsy specimens of intestinal mucosa from two pa-
ents with malabsorption were examined by routine
d electron microscopy, which demonstrated un-
spected giardiasis. Both specimens showed intact
testinal mucosa, but electron microscopy revealed
ardia lamblia within the lumen and in the inter-
llous spaces. The parasites were typically not
tached to the intestinal mucosa and frequently were
en in a crescent form. The trophozoites were sub-
quently recognized in the histologic sections as
escent-shaped bodies or cellular debris. Elec-
on microscopy is useful for the identification of
is parasite, since stool examinations in up to
% of the cases may be negative.

2660 SURFACE ULTRASTRUCTURE OF GIARDIAL INFESTATION. (Eng.) Tubbs, R. R.; Hawk, W. A. (Cleveland Clinic Foundation, Cleveland, OH). *Cleve. Clin. Q.* 43(4):293-299; 1976.

The light microscopic and surface ultrastructural features in a patient with giardial infestation and malabsorption were studied, the the patient's case report is presented. The patient, a 58-yr-old man, presented with left upper quadrant pain, belching, abdominal distension, and a 2-yr history of diarrhea and weight loss. *Giardia lamblia* cysts were detected in both the stool and in a specimen obtained by duodenal aspiration; the patient's symptoms resolved with metronidazole treatment. Light microscopy revealed *Giardia* trophozoites within the duodenal lumen and in the crypts; electron microscopy confirmed this and showed trophozoites lying free on the luminal surface. Mild to absent shortening of the microvilli was observed.

GENERAL

Regional Enteritis

2671 FERRITIN IN CROHN'S DISEASE TISSUE: DETECTION BY ELECTRON MICROSCOPY. (Eng.) Whorwell, P. J.; Baldwin, R. C.; Wright, R. (Southampton General Hosp., Southampton, SO9 4XY, England). *Gut* 17(9):696-699; 1976.

Attempts were made to visualize viral particles by electron microscopy in 12 specimens of Crohn's disease tissue and in stool preparations from nine patients with this disease. Four normal intestinal specimens and one small intestinal lymphoma were also studied. No viral particles were observed by either direct or immune electron microscopy in the tissue or the stool specimens. Abundant 12-nm particles of density 1.45 were found in all tissue specimens. Similar particles were found only occasionally in normal tissue. The particles were not clumped by Crohn's or normal sera. Negative stainin and electron microscopy of purified horse spleen ferritin revealed particles that were morphologicall identical to the 12-nm particles; in addition, radioimmunoassay demonstrated ferritin in those fractions of the gradient containing the particles, the levels showing a close correlation with the particle count. Since some diseased cells have an abnormally high rate of ferritin synthesis, the authors conclude that this is also the case in Crohn's disease.

2672 COLONIC PERFORATION IN CROHN'S DISEASE. (Eng.) Fisher, J.; Mantz, F.; Calkins, W. G. (1800 Sullivan Ave., Suite 304, Daly City, CA 94015). *Gastroenterology* 71(5):835-838; 1976.

The case reports of three patients with acute, free perforation of the colon in Crohn's disease are presented. The first patient, a 17-yr-old boy, had undergone an ileocolostomy for Crohn's disease 11 months previously; abdominal pain, diarrhea, and fever persisted postoperatively, in spite of management with corticosteroids, ACTH, and salicylazosulfapyridine. An emergency laparotomy revealed marked inflammation and omental adhesions at the previous anastomotic site between ileum and colon and a free colonic perforation just distal to the anastomosis. The perforation was closed, and the involved bowel was resected. The patient continues to have active inflammatory bowel disease 11 months after the reconstruction of the ileocolonic anastomosis, despite chemotherapy. The second patient, a 28-yr-old man, had a 4-yr history of Crohn's disease of the small and large bowel and had been maintained in remission on corticosteroids and salicylazosulfapyridine for two of those years. Severe abdominal pain led to an emergency laparotomy, which revealed inflammatory changes of the ileum and colon and a 5-mm free perforation in the sigmoid colon. A diverting colostomy was carried out, but a second operation was performed 22 days later because the patient developed multiple intra-abdominal abscesses. Two ileal perforations were found and closed, and a partial left colectomy was performed. The remaining colon was removed 4 weeks later, at which time no further perforations were found. Patient 3, a 64-yr-old man, had undergone an ileotransverse colostomy 15 yr previously for inflammatory bowel disease. One colonic perforation proximal to the splenic flexure and seven perforations in the mid descending colon were discovered at laparotomy following an episode of bloody diarrhea and abdominal pain. Pathologically, the perforations in this patient were thought to be due to exceedingly acute fulminating disease, with dissolution of the bowel wall at the base of relatively broad ulcers. This was the only patient with features suggesting toxic megacolon. In the first two patients, it appeared that the perforations resulted from indolent penetrating sinuses, which had not previously approached the serosal surface closely enough to incite the usual adhesive peritoneal inflammatory reaction.

2673 SERUM TRYPTOPHAN IN CROHN'S DISEASE. (Eng.) Beeken, W. L. (D-308 Given Building, Univ. Vermont, Burlington, VT 05401). *Scand. J. Gastroenterol.* 11(7):735-740; 1976.

2674 METASTATIC CROHN'S DISEASE. (Eng.) McCallum, D. I.; Gray, W. M. (Raigmore Hosp., Inverness, Scotland). *Br. J. Dermatol.* 95(5):551-554; 1976.

DHEW Publication No. (NIH) 78-66

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tra Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The numb and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

75 BIOCHEMICAL DIFFERENTIATION OF THE PLASMA
MEMBRANE OF THE INTESTINAL EPITHELIAL
LL. (Eng.) Michell, R. H.; Coleman, R.; Lewis,
A. (Dept. Biochemistry, Univ. Birmingham, P.O.
x 363, Birmingham B15 2TT, England). *Biochem.
c. Trans.* 4(6):1017-1020; 1976.

e biochemical differentiation of the plasma mem-
ane of enterocytes is reviewed. The study of
ush border preparations reveals a membrane with a
riety of terminal digestive hydrolases attached
its luminal surface; these hydrolases are heavily
ycosylated and are moored to the membrane by
latively small hydrophobic polypeptide segments.
the cytoplasmic surface of the brush border mem-
ane, and attached to it by α-actinin bridges, is
actin array that forms the microvillus core,
ich also interacts with myosin-like proteins in
e terminal web. It is possible that the brush
rder is motile and that its motility facilitates
s digestive and absorptive function. Enzyme stud-
s have indicated that the brush border and baso-
teral regions of the plasma membrane have distinct
mplements of enzymes. Analysis of the lipids of
e two plasma membrane regions of the guinea pig
terocyte has shown that the lipids of both regions
e rich in cholesterol, sphingolipids, and glycero-
ids.

76 LAMELLATED OSMIOPHILIC BODIES IN MOUSE
GALLBLADDER EPITHELIUM. (Eng.) Neval-
ien, T. J.; Dean, S.; Jokelainen, P. T.; Laitio,
(Lab. Electron Microscopy, Univ. Turku, Kiinamyl-
katu 10, 20520 Turku 52, Finland). *Acta Anat.
sel)* 96(4):486-496; 1976.

e ultrastructure of C57BL/10J mouse gallbladder
thelium was studied by electron microscopy, with
ecial attention to dense cytoplasmic bodies.
erogeneous dense bodies with osmiophilic and
se granular components were identified. Many of
se bodies consisted of lamellated osmiophilic
uctures, similar to the phospholipid bodies of
large alveolar (type II) cells of the mammalian
g. The dense bodies containing the lamellar
uctures were membrane-limited and 0.5-1.0 μm in
meter. They were located in the supranuclear
oplasm and were often closely associated with the
gi apparatus. Acid phosphatase activity was
onstrated within these bodies and in some of the
gi vacuoles. The contents were disposed in con-
tric lamellar osmiophilic structures, sometimes
earing as scroll-like configurations. These
dings suggest that phospholipid absorbed from
gallbladder lumen is stored in phagosomes in the
tral cytoplasm of the gallbladder epithelial cells.

7 MORPHOMETRIC ANALYSIS OF RAT HEPATOCYTES
AFTER TOTAL BILIARY OBSTRUCTION. (Eng.)
es, A. L.; Schmucker, D. L.; Mooney, J. S.;
er, R. D.; Ockner, R. K. (Veterans Admin. Hosp.,
4150 Clement St., San Francisco, CA 94121). *Gastroenterology* 71(6):1050-1060; 1976.

The effects of 48-hr extrahepatic biliary obstruction on hepatocyte structure were examined by light and electron microscopy in male Sprague-Dawley rats. Obstruction was produced by doubly ligating the common bile duct immediately distal to its origin and dividing it between the two ligatures. Liver cells near the portal area were compared with those in the centrilobular regions of the hepatic lobule. Observations in normal animals confirmed earlier evidence of quantitative differences in the surface density of organelles in hepatocytes from different regions of the lobule. The portal cells contained a significantly greater quantity of Golgi complex than centrilobular hepatocytes. After 48 hr of total obstruction, morphometric analysis revealed that the volume of Golgi in the portal hepatocytes was reduced to one-half that of control values. A similar decrease in the surface area of the Golgi membranes in the portal cells was observed in the cholestatic livers. After biliary obstruction, there was a marked decrease in the total amount of endoplasmic reticulum membrane in both the central and portal cells. In all zones, a decrease in the volume density of mitochondria and lysosomes was noted, whereas the volume of microbodies was increased. The loss in total membrane material within the cell may be secondary to the degranulation and decrease in total surface area of rough endoplasmic reticulum, an organelle thought to be responsible, in part, for the synthesis of new cellular membranes. These observations suggest that present concepts of the pathogenesis of cholestatic liver disease require reappraisal.

2678 DISTRIBUTION OF ORGANELLES AND MEMBRANES BETWEEN HEPATOCYTES AND NONHEPATOCYTES IN THE RAT LIVER PARENCHYMA: A STEREOLOGICAL STUDY. (Eng.) Blouin, A.; Bolender, R. P.; Weibel, E. R. (Faculty Veterinary Medicine, Univ. Montreal, Saint-Hyacinthe, Quebec, Canada). *J. Cell Biol.* 72(2):441-455; 1977.

A systematic stereological analysis of liver parenchyma was carried out to determine the distribution of organelles and membranes between hepatocytic and endothelial, Kupffer, and fat-storing cells (nonhepatocytes). Sprague-Dawley rat livers were fixed by vascular perfusion, and the data were corrected for systematic errors due to section thickness and compression. The extracellular space compartment included the lumina of sinusoids (10.6%), the space of Disse (4.9%), and the bile canaliculi (0.4%). Hepatocytes constituted 78% of parenchymal volume; the nonhepatocytes accounted for 6.3% and consisted of 2.8% endothelial cells, 2.1% Kupffer cells, and 1.4% fat-storing cells. The nonhepatocytes contributed 55% of the volume of lipid droplets in the liver, 43% of the lysosomes, and 1.2% of the mitochondria. Although the nonhepatocytes accounted for only 8% of the total surface area of parenchymal membranes, they contained 26.5% of all the plasma membranes, 32.4% of the lysosomal membranes, 15.1% of the Golgi apparatus, 6.4% of the endoplasmic reticulum, and 2.4% of the mitochondrial membranes. The data demonstrate the extent to which nonhepatocytic organelles can contaminate subcellular fractions used for biochemical studies. Particularly important for the interpretation of studies on lysosomes, plasma membrane, and Golgi apparatus is the finding that an appreciable part of these organelles may be derived from cell types other than hepatocytes.

2679 EXOCRINE PANCREAS UNDER EXPERIMENTAL CONDITIONS. III. MEMBRANE AND CELL JUNCTIONS IN ISOLATED ACINAR CELLS. (Eng.)

Metz, J.; Forssman, W. G.; Ito, S. (Anatomisches Institut III, Im Neuenheimer Feld 307, D-6900 Heidelberg, W. Germany). *Cell Tissue Res.* 177(4): 459-474; 1977.

The ultrastructure of the cell membrane and intercellular junctions was studied after the isolation of rat exocrine pancreatic cells by tryptic digestion and mechanical treatment. The number and distribution of membrane-associated particles did not change significantly when acinar cells *in situ* were compared to those after the isolation procedure. However, intercellular junctions underwent distinct alterations. Gap junctions in normal pancreatic cells were macular in shape and localized at the lateral parts of the cell membrane. In isolated acinar cells, gap junctions were irregularly shaped, more extended, and frequently associated with tight junctions. Tight junctions formed belt-like structures that persisted after isolation, but subsequently became elongated and interrupted. Thus, extensive macular areas of tight junctions developed. The strands on the P-face and the grooves on the E-face of freeze-fracture replicas changed in array, dissociated, and became loosely packed on large membrane areas. The intramembranous proteins of tight and gap junctions are mobile structures within the fluid membrane. The shape of their array is dependent on the form of the intercellular contact zone.

2680 SCANNING ELECTRON MICROSCOPY OF DISSOCIATED PANCREATIC ACINAR CELL SURFACES. (Eng.)

Motta, P.; Andrews, P. M.; Caramia, F.; Correr, S. (Istituto di Anatomia umana normale, Universita' di Roma, Viale Regina Elena, 289, I-00161 Rome, Italy). *Cell Tissue Res.* 176(4):493-504; 1977.

The pancreatic acinar cell surfaces of adult rats and Rhesus monkeys were studied by scanning electron microscopy (SEM) with a dissection technique and were correlated with results obtained by transmission electron microscopy (TEM). The SEM results demonstrated characteristic arrangement of microplicae, which in some areas were densely packed. In many areas, the microplicae were distributed in such a manner that they created zones with typical geometrical shapes and showed a relatively smooth surface. These smooth areas may coincide, with the limits of intimate contact between adjacent acinar cells, which, in turn represent part of the junctional complex. SEM preparations revealed the presence of groups of densel packed microplicae, arranged in regular rows and distributed along some grooves and/or infoldings of the cellular surface. On the basis of SEM and TEM information, it is likely that these structures correspond to intercellular (and possibly, in some cases, intracellular) canaliculi, which topographically form a kind of extensive microlabyrinthine arrangement runni along all the cell sides. Spherical zymogen droplets were found within the vesicles of the Golgi complex. Because these vesicles appeared to be connected by small openings, in many scanning images they may repre sent a system of intercommunicating chambers (vacuole through which the zymogen droplets can be continuousl accumulated and discharged into the acinar lumen.

2681 THE EFFECT OF FIXATION CONDITIONS ON THE ULTRASTRUCTURAL APPEARANCE OF GASTRIN CELL GRANULES IN THE RAT GASTRIC PYLORIC ANTRUM. (Eng.)

Mortensen, N. J. M.; Morris, J. F. (Medical Sch., University Walk, Bristol BS8 1TD, England). *Cell Tissue Res.* 176(2):251-263; 1977.

The ultrastructural appearance of gastrin cell (G cell) granules from Wistar rats was studied after different fixation procedures. When the pH of prefixation was varied, there was greater preservation of the electron density of granule cores after acidi (pH 5.0 and 6.0) than after neutral or alkaline (pH 7.0 and 8.0) prefixation. Increasing the duration o prefixation at pH 7.3 resulted in a progressive loss of electron density of the granule core, with swelling and occasional rupture of the limiting membrane In tissues where most granules had been rendered ele tron lucent by fixation, granules that remained dens cored were preferentially located close to the Golgi zone. These findings indicate that the electron der sity of G cell granules is profoundly affected by co ditions of fixation and that immature granules are more resistant to loss of core density than are matu granules. The gastrin granule *in vivo*, like other polypeptide granules, may have a "solid," osmoticall inactive core.

2682 ULTRASTRUCTURAL AND CARBOHYDRATE HISTOCHE ICAL STUDIES ON THE DIFFERENTIATION AND R NEWAL OF MUCOUS CELLS IN THE RAT GASTRIC FUNDUS.

(Eng.) Wattel, W.; Geuze, J. J.; de Rooij, D. G. (Center for Electron Microscopy, State Univ., Nicol Beetsstraat 22, Utrecht, Netherlands). *Cell Tissue Res.* 176(4):445-462; 1977.

The histochemistry and ultrastructure of Wistar rat gastric surface mucous cells (SMC) and mucous neck cells (MNC) and their undifferentiated and immature precursors were studied. The secretory granules o SMC were smaller, more electron dense, and more reactive to PAS and its analogues than those of MNC. Alcian blue staining demonstrated that the mucus o SMC was acidic and that of MNC was neutral. The p iodic acid-thiocarbohydrazide-silver proteinate method revealed the presence of carbohydrates in the Golgi apparatus, condensing vacuoles, secre-

ry granules, apical vesicles and tubules, and
ll coat. Maturation of SMC during their mi-
ation toward the free surface was reflected by an
crease of rough endoplasmic reticulum and microfila-
nts, and a decrease of microvilli and apical vesicles
d tubules. The secretory granules of older SMC were
ss acidic and possessed a proteinaceous core. Most
C were fully differentiated, but some immature MNC
ntaining only a few granules were found. Further-
re, undifferentiated cells and intermediates between
C and MNC were also observed. The presence of both
ansitional and intermediate forms indicates that
th SMC and MNC arise from the same population of
differentiated cells. Incorporation of [^{3}H]thymidine
vealed that undifferentiated cells, isthmic SMC,
C, and intermediate cells are proliferative. No
oliferative activity was found in foveolar SMC,
rietal, chief, fibrillovesicular, or endocrine
lls.

83 STEREOLOGICAL CHANGES IN RAT PARIETAL CELLS AFTER VAGOTOMY AND ANTRECTOMY. (Eng.)

lander, H. F. (Dept. Anatomy, Univ. Umea, Umea,
eden). *Gastroenterology* 71(6):1010-1018; 1976.

e quantitative aspects of parietal cell ultrastruc-
re were studied in 44 normal, vagotomized, and an-
ectomized male Sprague-Dawley rats. The animals
re divided into seven groups: normal fasted, normal
nfasted, 4 weeks after vagotomy, 10 weeks after
gotomy and pyloroplasty, 10 weeks after pyloroplasty,
weeks after antrectomy, and 10 weeks after antrec-
my. Stereological data were obtained from 30-40
rietal cells in each animal. In the normal nonfast-
rats, the parietal cells high up in the glands had
larger secretory surface density than those at deep-
levels of the mucosa. Neck parietal cells contain-
g a few mucous granules constituted about 10% of
e total number of parietal cells in the normal rats;
ey were most common in the midgland region. The
erage parietal cell volume in the normal fasted rats
s calculated to be 1,100 μ^3; the cells were signifi-
ntly smaller 10 weeks after vagotomy and pyloroplas-
and still smaller 10 weeks after antrectomy. In
is respect, the results after vagotomy and pyloro-
asty did not differ from those after pyloroplasty
one. The parietal cell density in the normal fasted
ts averaged 144 x 10^3 cells/mm^3; in the operated
ts (except for the 4-week vagotomized rats) the
lls were more numerous. The parietal cell volume
nsity was about equal in all groups of animals, ex-
pt for the 10-week antrectomized rats, where a signi-
cant reduction occurred. A thinner mucosa with more,
t smaller, parietal cells is a morphological alter-
ion which may help to explain the drop in acid-pro-
cing capacity after antrectomy.

84 IMMUNOCYTOCHEMICAL EVIDENCE FOR GLUCAGON-CONTAINING CELLS IN THE HUMAN STOMACH.

ng.) Barragan, L. M.; Rufener, C.; Srikant, C. B.;
bbs, R. E.; Shannon, W. A., Jr.; Baetens, D.;
ger, R. H. (Dept. Anatomy, Faculty Medicine, Sala-
nca, Spain). *Horm. Metab. Res.* 9(1):37-39; 1977.

Evidence for the existence of fundal glucagon-containing cells was sought by immunocytochemical techniques in stomachs obtained at autopsy from eight patients without gastric disease. The direct immunoperoxidase technique, using antiglucagon serum 30K, demonstrated glucagon-containing cells in only one of the eight gastric fundi. These cells were located between parietal cells on the basement membranes and did not appear to reach the lumenal surface of the oxyntic glands. In the two sections from this patient, one contained 9 and the other 16 such cells. The specimen from this patient had been taken only 2-3 hr after death, whereas the other specimens had been taken up to 4 hr after death. The patient was also pregnant. To study the effect of the postmortem interval on fundic glucagon, the glucagon content of canine fundus (in which glucagon-containing cells were previously identified) was studied immediately after death and after 4 hr at room temperature. There was a marked loss of glucagon immunoreactivity after 4 hr, which may explain the low glucagon content in the postmortem tissues of man.

2685 LESIONS OF EXPERIMENTALLY INDUCED COLIBACILLOSIS IN NEONATAL GNOTOBIOTIC PIGS: A SCANNING ELECTRON MICROSCOPIC STUDY.

(Eng.) Newman, L. E.; Trapp, A. L.; Waxler, G. L. (Dept. Large Animal Surgery and Medicine, Michigan State Univ., East Lansing, MI 48824). *Am. J. Vet. Res.* 38(3):297-305; 1977.

Scanning electron and light microscopy were used in studies of stomach, doudenum, cranial, and caudal portions of the jejunum, ileum, cecum, and spiral colon from 18 gnotobiotic pigs to determine if any characteristic changes occurred in or on the surface of the intestinal tract as a result of *Escherichia coli* infection. Five dogs were raised as controls and 13 received 1.6 x 10^6 colony-forming units of *E. coli* 0138:K81:NM p.o. at 6 days of age. Infiltration of WBC into the stomach mucosa was seen by light microscopy. Scanning electron microscopy revealed an irregular pattern of the mucosal surface of the stomach, formed by the gastric pits and the mucosal extensions on the individual rugae. Sections of the ileum from control and infected pigs contained collapsed cells around the extrusion zone at the tips of the villi. These collapsed cells were more numerous in infected pigs and appeared to have sloughed from the area of the extrusion zone, resulting in exposure of the lamina propria. Cecum and spiral colon were free of changes. Alterations of the mucosa of the intestinal tract of gnotobiotic pigs infected with *E. coli*, visualized by scanning electron microscopy, were considered to be too inconsistent to be of diagnostic significance.

2686 ULTRASTRUCTURAL ORGANIZATION OF THE ENTEROCHROMAFFIN CELLS OF THE DUODENAL MUCOUS MEMBRANE AFTER VAGOTOMY.

(Rus.) Eletsky, Iu. K.; Starkova, E. S. (N. I. Pirogov Second Moscow Medical Inst., Moscow, USSR). *Biull. Eksp. Biol. Med.* 82 (9):1131-1133; 1976.

2694 ELECTRICAL PROPERTIES AND ACTIVE SOLUTE TRANSPORT IN RAT SMALL INTESTINE. I. POTENTIAL PROFILE CHANGES ASSOCIATED WITH SUGAR AND AMINO ACID TRANSPORTS. (Eng.) Okada, Y.; Tsuchiya, W.; Irimajiri, A.; Inouye, A. (Kyoto Univ. Sch. Medicine, Kyoto 606, Japan). *J. Membr. Biol.* 31(3):205-219; 1977.

The transepithelial potential difference (PD_t) and the mucosal membrane potential (V_m) were measured in preparations of rat duodenum, jejunum, or ileum. When D-glucose (20 mM) was added to the mucosal fluid, there was a significant depolarization of the V_m and an increase in PD_t. L-glucose did not affect these parameters. Glycine (20 mM) applied to the mucosal side induced V_m depolarization and PD_t increment in ileal sheets only. When ouabain (3×10^{-4} M) was added to the serosal fluid or when phlorizin (10^{-4} M) was added to the mucosal fluid, the glucose dependent changes in PD_t and V_m were inhibited. After analyzing the results with an equivalent circuit model for the epithelium, it was concluded that the active transport of glucose and glycine involves both a depolarization of the mucosal membrane and a hyperpolarization of the serosal membrane. The latter was attributed to the activation of the serosal electrogenic sodium pump by Na^+ cotransported into the cell.

2695 ELECTRICAL PROPERTIES AND ACTIVE SOLUTE TRANSPORT IN RAT SMALL INTESTINE. II. CONDUCTIVE PROPERTIES OF TRANSEPITHELIAL ROUTES. (Eng.) Okada, Y.; Irimajiri, A.; Inouye, A. (Kyoto Univ. Sch. Medicine, Kyoto 606, Japan). *J Membr. Biol.* 31(3):221-232; 1977.

The transepithelial resistance (R_t), cell membran resistance (r_M), and ratio of serosal (r_s) to muc (r_m) cell membrane resistances were measured in r small intestine using lucite chambers and microel trodes. The addition of D-glucose (20 mM) or gly (20 mM) to the mucosal fluid did not affect the v obtained. An equivalent circuit analysis was use estimate the quantitative contribution of the ext cellular shunt pathway to the total transepitheli conductance. This estimated value of ≈95% was in accord with values obtained for other "leaky" epithelia and remained unaffected by the active transport of D-glucose or glycine. These results support the conclusion that the electric potential changes associated with active transport can be ascribed solely to changes in membrane electric charge: a depolarization of the mucosal membrane and a hyperpolarization of the serosal membrane.

6 EFFECT OF AMILORIDE ON ELECTRICAL ACTIVITY AND ELECTROLYTE TRANSPORT IN HUMAN COLON.

n Na$^+$ are involved in generating an electrical po-
tial difference (PD) across the human colonic wall.
control preparations, the short circuit current
$_c$) was 2.9 μEq/hr/cm^2, while the net transfer of
and Cl$^-$ was 4.6 and 1.4 μEq/hr/cm^2, resp., and the
idual ionic flux was near zero. When 10^{-3} M ami-
ide was added to the mucosal side of the membrane,
I_{sc} decreased to 0.7 μEq/hr/cm^2, and the net Na$^+$
nsfer dropped to 3.4 μEq/hr/cm^2. The Cl$^-$ flow in
h directions was unchanged, while the residual
ic flux increased significantly. Rectal instil-
ion of 10^{-3} M amiloride in 13 normal subjects
sed a drop in PD from -46 mV to -27 mV, with a half
e of less than 13 sec. It is proposed that the
n counter ions for active Na$^+$ transport may be H$^+$
m mucosa to serosa and/or HCO$_3^-$ from serosa to mu-
a.

7 EFFECT OF PEPSIN ON IONIC PERMEABILITY OF CANINE ESOPHAGEAL MUCOSA. (Eng.) Safaie-
:azi, S. (Univ. Iowa Coll. Medicine, Iowa City,
52242). *J. Surg. Res.* 22(1):5-8; 1977.

pathogenesis of peptic esophagitis produced by
sin was clarified in a study of the effect of
sin on the permeability of canine esophageal muco-
The mean rate of hydrogen ion loss across the
osa of distally occluded esophagus perfused with
nEq/l HCl (-0.12 ± 0.02 mEq/30 min) or 100 mEq/l
(-0.49 ± 0.16 mEq/min) was increased to -0.30 ±
mEq/l when 7,500 U of pepsin was added to the
er HCl concentration; the addition of 15,000 U of
sin to this concentration increased the H$^+$ loss
0.23 ± 0.11 mEq/l. At 50 mEq/l HCl and 7,500 U
epsin, the H$^+$ loss was -0.92 ± 0.09 mEq/l (p<
2), but when the concentration of pepsin was in-
ased to 15,000 U, the H$^+$ loss was decreased to -0.65
04 mEq/l ($p<0.01$). The loss of H$^+$ was increased
.17 ± 0.17 mEq/30 min ($p<0.001$) when 7,500 U
epsin were added to 100 mEq/l HCl, but a decline
he amount of H$^+$ loss was noted when the concen-
ion of pepsin was increased to 15,000 U ($p<0.01$).
sin disrupts the esophageal mucosal barrier, and
observation suggests that reflux esophagitis in
s of incompetent gastroesophageal sphincter may
ue to increased permeability of the mucosa to H$^+$
ced by pepsin.

SEQUENTIAL UPTAKE OF HORSERADISH PEROXIDASE BY LYMPHOID FOLLICLE EPITHELIUM OF
R'S PATCHES IN THE NORMAL UNOBSTRUCTED MOUSE IN-
INE: AN ULTRASTRUCTURAL STUDY. (Eng.) Owen, R.
Veterans Admin. Hosp., [151E], 4150 Clement
San Francisco, CA 94121). *Gastroenterology*
):440-451; 1977.

eradish peroxidase (HRP) was injected into the
gated intestines of fasted healthy 2-month-old
e Swiss mice to determine whether it would be ab-
ed in detectable quantities by membranous epithelial cells of the lymphoid follicle epithelium of Peyer's patches (M cells), and whether subsequent uptake of HRP by lymphocytes could be documented. At 1- to 60-min intervals, the most distal ileal Peyer's patch was fixed, removed, reacted with H_2O_2-3,3'-diaminobenzidine, and examined by light and electron microscopy for HRP reaction product. At 1 min, HRP adhered to surfaces of columnar cells and M cells and extended down into surface pits in the M cell. After 5 min, HRP was found in vesicles of M cells, but not in columnar cells. At 1 hr, HRP was detected in the extracellular space between M cells and their enfolded lymphocytes, as well as in vesicles within these lymphocytes. Transport of intestinal luminal material by M cells, with subsequent uptake by lymphocytes, provides a specific route for antigen uptake into the intestinal lymphoid system.

2699 THE EFFECTS OF HYPOTHYROIDISM AND FASTING ON ELECTROGENIC AMINO ACID TRANSFER: POSSIBLE EVIDENCE FOR MULTIPLE NEUTRAL AMINO ACID CARRIER SYSTEMS IN RAT JEJUNUM. (Eng.) Syme, G.; Levin, R. J. (Dept. Physiology, The Univ., Sheffield, S10 2TN Yorkshire, England). *Biochim. Biophys. Acta* 464(3):620-628; 1977.

Everted jejunal sacs were prepared in fed or fasted hypothyroid male Sheffield rats, and membrane potential differences were measured when neutral amino acids were added to the mucosal fluid. The maximum potential generated (PD_{max}) and the K_m were compared to normal values from fed euthyroid rats. Valine transfer in fed hypothyroid rats induced an increase in the PD_{max} of 61%, but the K_m was unaffected, as compared to controls; the opposite was true for alanine, where the K_m was reduced by 24% and the PD_{max} was unaffected. Sarcosine reduced both these parameters. In fasted hypothyroid rats, valine and sarcosine reduced the K_m, while the PD_{max} was unaffected. Alanine caused a small increase in the PD_{max} and an unaltered K_m. Only alanine transfer was affected in fasted euthyroid rats, with both the PD_{max} and the K_m being reduced by 30% and 53%, resp. Values for leucine and methionine were not affected by fasting and/or hypothyroidism. These results seem to indicate the presence of at least three separate transfer mechanisms for neutral amino acids and one for sarcosine.

2700 SIGNIFICANCE OF Ca-SOAP FORMATION FOR CALCIUM ABSORPTION IN THE RAT. (Eng.) Gacs, G.; Barltrop, D. (St. Mary's Hosp. Medical Sch., London, W2 1PG, England). *Gut* 18(1):64-68; 1977.

The significance of calcium soap formation in the inhibition of calcium absorption was studied in rats. ^{47}Ca-labeled soaps of fatty acids were introduced into the duodenum, and the absorption of calcium was measured after 4 hr in a whole-body counter. The absorption of calcium was inversely correlated with the chain length of the fatty acid, varying from 1% for Ca-stearate to 60% for Ca-hexanoate. Increasing the degree of unsaturation of the fatty acid was accompanied by increased calcium absorption. The availability of calcium for absorption from the soaps was correlated with their solubility in 1% aqueous Na-tauroglycocholate. The percentages of calcium as soap in the small intestine and the feces after intragastric administration of calcium and fats were similar, suggesting that the fecal content of calcium soaps is an index of intestinal soap formation. Soap formation was negligible when $CaCl_2$ was given with tristearate, trioleate, or tridecanoate, and no depression of calcium absorption was observed; soap formation was marked (47.7 ± 16.6% in feces, 69.2 ± 16.0% in intestine) with stearic acid. Calcium absorption was markedly impaired by the addition of phosphates at a Ca:P ratio of 1:1, irrespective of the presence of neutral fats. Calcium absorption was reduced with stearic acid. The degree of Ca-soap formation and the inhibition of calcium absorption were well correlated. The results suggest that, although calcium soap formation may markedly depress calcium absorption in the rat, no significant soap formation takes place when fats are given in the form of triglycerides.

2701 INTESTINAL MITOCHONDRIAL CALCIUM UPTAKE DURING ADAPTATION TO DIETARY CALCIUM RESTRICTION. (Eng.) Krawitt, E. L.; Kunin, A. S.; Bacon, B. F. (Dept. Medicine, Univ. Vermont, Burlington, VT 05401). *Calcif. Tissue Res.* 21(2):129-133; 1976.

To evaluate the role of mitochondrial calcium uptake in intestinal calcium absorption, the effect of adaptation to dietary calcium deficiency on the *in vitro* uptake of calcium by duodenal mitochondria isolated from cockerels was studied. The birds used had received a diet adequate in vitamin D_3 and phosphate and 1.0% Ca for the first 9 days of life. For the next 8 days, the chicks received a diet containing 1.20% Ca, and for 10 days after that, they received either 1.20% or 0.08% Ca in the diet. The uptake of ^{45}Ca by mitochondria isolated from chicks deprived of dietary calcium was not significantly different from that of controls ($p>0.05$) at any time interval (0.5-20 min). The results suggest that increased calcium uptake by intestinal mitochondria is not crucial for adaptation to a low calcium diet.

2702 STUDY OF THE EFFECTS OF A CARBOHYDRATE AND A PHOSPHATE ON THE ABSORPTION OF CALCIUM IN INTESTINAL LOOPS IN SITU. (Fre.) Dupuis, Y.; Fournier, A.; Fournier, P. (Physiologie, Faculte de Pharmacie, 92290 Chatenay-Malabry, France). *C. R. Soc. Biol. (Paris)* 170(2):304-309; 1976.

The effects of L-xylose and sodium phosphate on the absorption of calcium chloride were examined in the ligated jejunum and ileal loops of rats *in vivo*. Isolated jejunal loops were injected with ^{45}Ca-labeled $CaCl_2$ to which graded doses of sodium phosphate (5, 10, 20, and 50 mM) had been added. The rats were sacrificed 3 hr after injection. The absorption coefficient of $CaCl_2$ fell from 49.4 ± 1.9% in the control animals to 36.3 ± 1.8, 29.1 ± 1.3, 19.0 ± 1.3, and 14.9 ± 1.4% with increased doses of sodium phosphate. In another series, L-xylose (10, 30, 70, and 150 mM) was injected into the ileum of young rats in a 20 mM $CaCl_2$ solution. The control absorption coefficient of $CaCl_2$ (24.8 ± 3.6%) was enhanced by increased doses of L-xylose to 70.8 ± 5.3% at a 150 mM dose. The calcium absorption curves were dependent on the dose of phosphate or carbohydrate and were simi
to those that account for the effect of activators
inhibitors on enzyme activity. The mechanisms of t
xylose activation and the phosphate inhibition of c
cium absorption have yet to be determined.

2703 SITE OF IRON ABSORPTION AS DETERMINED BY DIRECT INTESTINAL ^{59}Fe DOSING OF INTACT RATS. (Eng.) Ansari, M. S.; Miller, W. J.; Neathery, M. W.; Lassiter, J. W.; Gentry, R. P. (Dept. Animal and Dairy Science, Univ. Georgia, Athens, GA 30602). *Nutr. Rep. Int.* 15(1):37-40; 1977.

The iron absorption site(s) in the small intestine
of intact rats was studied under normal physiologi
conditions. $^{59}FeCl_3$ (20 μCi) was injected directly
into the small intestines of 46 Sprague-Dawley rats. Iron absorption was determined by comparing ^{59}Fe retention of the liver, kidneys, muscle, heart, tibia, spleen, blood, and whole-body carcass (with the intestinal tract removed) at 24 hr after dosing. Tissue ^{59}Fe was plotted against the site of injection expressed as a percentage of small intestinal length from proximal to distal end. A curvilinear relationship existed between tissue ^{59}Fe and dosing site, with about 90% of the dose being absorbed in the proximal 20% of the small intestine. The results demonstrate that the duodenum is the primary iron absorption site in rats.

2704 EFFECT OF IRON SATURATION OF TRANSFERRI
ON HEPATIC IRON UPTAKE: AN IN VITRO ST
(Eng.) Zimelman, A. P.; Zimmerman, H. J.; McLean
R.; Weintraub, L. R. (Veterans Admin. Hosp., 150
South Huntington Ave., Boston, MA 02130). *Gastro-enterology* 72(1):129-131; 1977.

The effect of percentage of transferrin saturatio
and total iron concentration on the rate of iron
uptake was studied in perfused rat livers. After
45 min, there was no significant difference in i
uptake by livers perfused with 46% or 78% iron-
saturated transferrin, with the total iron conte
kept constant at 13.8 ± 1.2 μg. However, raising
the concentration of iron from 7.0 to 14.6 μg in
the perfusate while maintaining a constant satur
tion of transferrin (47.0 ± 4%) increased the ir
uptake by 66% ($p<0.001$). At similar concentrati
of iron and transferrin saturation, iron-deficie
livers took up greater amounts of iron than did
normal livers; the uptake with a constant iron
concentration or with a constant transferrin concentration in the perfusate was twice that in th
normal liver. The results show that the hepatic
uptake of transferrin-bound iron is determined b
the concentration of iron in the perfusate and b
the status of iron stores in the liver being perfused.

2705 GASTROINTESTINAL ABSORPTION OF ^{95}Nb BY
OF DIFFERENT AGES. (Eng.) Mraz, F. R
Eisele, G. R. (Comparative Animal Res. Lab., 129

ethel Valley Rd., Oak Ridge, TN 37830). *Radiat. es.* 69(3):591-593; 1977.

he gastrointestinal absorption of ^{95}Nb was compared n juvenile and adult rats, and its duration in the igestive tract was determined. Carrier-free ^{95}Nb n oxalic acid was administered via gavage to rats 6 r-129 days of age, and these were sacrificed 4 days ater. Rats less than 6 hr old were dosed in the ame manner and sacrificed 1, 4, 5, 7, 9, 12, 15, 17, 9, or 21 days later. Significantly more ^{95}Nb was ound in the gastrointestinal tracts and the tissues f the 6-hr-old rats (47.5% and 5.54%, resp.) and the -day-old rats (21.8% and 3.86%, resp.) than in the astrointestinal tracts and tissues of the 21-day-old 0.015% and 0.088%, resp.) and 129-day-old rats 0.007% and 0.091%, resp.). In the pups dosed before he age of 6 hr, the greatest body content was found at days after dosing (6.6%) and was significantly highr than that found during the first 5 days after adinistration. The amount of ^{95}Nb in the gastrointesinal tract with its contents, however, decreased proressively from about 62% of the dose at day 1 to bout 20% at 9 days. At 15 days, the amount in the ody was significantly lower (4.6%, $p<0.01$) than at 9 r 12 days, while the gastrointestinal ^{95}Nb values ontinued to decline. The relatively high absorption f ^{95}Nb by the suckling pup and the long residence ime in the gastrointestinal tract indicates that ^{95}Nb s more hazardous in the juvenile than in the adult.

706 THIAMINE TRANSPORT BY HUMAN INTESTINE IN VITRO. (Eng.) Rindi, G.; Ferrari, G. Inst. Human Physiology, Univ. Pavia, via Forlanini , I-27100 Pavia, Italy). *Experientia* 33(2):211-13; 1977.

hiamine transport was studied in human gastroinestinal mucosa (stomach, small intestine, and ransverse colon) and muscle incubated *in vitro* with 2-^{14}C]thiamine-thiazole. At the start of incubaion, unlabeled (endogenous) free thiamine content anged from 0.40 to 0.21 nmol/ml tissue water in the ucosa and from 0.13 to 0.17 nmol/ml in muscle. hereafter, thiamine uptake increased against a conentration gradient in mucosa and decreased in smooth uscle. Only the small intestine, particularly the jeunum, had the ability to accumulate labeled thiamine uring the incubation. Thiamine was accumulated in he phosphorylated form. The results demonstrate the resence of an active thiamine transport mechnism in the human small intestine.

707 THE INTESTINAL MUCOSAL BARRIER TO INTACT ANTIGENIC PROTEIN: DIFFERENCE BETWEEN OLON AND SMALL INTESTINE. (Eng.) Warshaw, A. L.; ellini, C. A.; Walker, W. A. (Massachusetts Generl Hosp., Boston, MA 02114). *Am. J. Surg.* 133(1): 5-58; 1977.

he absorption of intact bovine serum albumin (BSA), nown to be orally antigenic in rats, was measured nd compared in the colon and small intestine of oltzman rats. ^{3}H-BSA (50 mg/kg) was infused into ither the duodenum or ascending colon, and a samle of mixed peripheral blood was obtained 3 hr later. Albumin absorption from the small bowel in 10 rats averaged 1.7% of the total infused. Colonic absorption, measured in eight rats, was 0.13% of the infused dose, which was significantly less ($p<0.001$) than in the small intestine. These studies support the possibility that uptake of ingested or bacterial antigens from the normal gut may be involved in the pathogenesis of local intestinal and systemic disease in man. This study, in demonstrating that colonic mucosal barrier, as well as that of the small intestine, is normally permeable to protein, provides a basis for considerations of the pathogenicity of proteins that originate in the colonic lumen.

2708 IN VITRO STUDIES OF INTESTINAL ENDOTOXIN ABSORPTION. I. KINETICS OF ABSORPTION IN THE ISOLATED EVERTED GUT SAC. (Eng.) Nolan, J. P.; Hare, D. K.; McDevitt, J. J.; Ali, M. V. (Buffalo General Hosp., 100 High St., Buffalo, NY 14203). *Gastroenterology* 72(3):434-439; 1977.

The mucosal to serosal unidirectional flux of endotoxin was measured quantitatively with the use of an *in vitro* rat gut sac preparation. ^{51}Cr-labeled endotoxin (0.05-2.0 mg/ml) was placed in the mucosal bath. Over a 2-hr period, a small amount of endotoxin was transported transmurally, which was shown chromatographically to be similar to the starting material and which retained its toxic and immunogenic properties. The presence of 2.0 mg/ml of endotoxin in the mucosal bath did not significantly alter the tissue histology or permeability to 3-*O*-methyl-D-glucose. When unidirectional fluxes were measured, the flux was not proportional to the endotoxin concentration, as would be expected with a passively permeable solute, but rather its transport system became "saturated," displaying a maximum transport rate of 4.72 μg/cm/2 hr and a K_m of 0.425 mg/ml. The isolated gut sac provides an excellent model for the precise study of factors involved in endotoxin absorption.

2709 CHOLINE INFLUX ACROSS THE BRUSH BORDER OF GUINEA PIG JEJUNUM. (Eng.) Kuczler, F. J.; Nahrwold, D. L.; Rose, R. C. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA 17033). *Biochem. Biophys. Acta* 465:131-137; 1977.

Choline uptake across the mucosal border of guinea pig jejunum was measured to determine the characteristics of this step in intestinal absorption. Unidirectional influx of ^{14}C-choline appeared to proceed primarily by a saturable, carrier-mediated process at low mucosal choline concentrations; at high concentrations (>4 mM) the influx rate is approximately linearly related to the mucosal choline concentration, suggesting that absorption by passive diffusion predominates. Influx was only minimally reduced by elimination of Na^+ from the mucosal test solution or by reduction of the intracellular Na^+ concentration. Preincubation of tissue samples with metabolic inhibitors (2,4-dinitrophenol, 0.1 mM; cyanide, 2.0 mM) or with ouabain (0.1 mM) did not markedly reduce influx. These results are consistent with a model of choline transport across the brush border membrane by a carrier-mediated mechanism similar to that involved in fructose absorption, but different from the Na^+-dependent mechanism participating in active transport of sugars and amino acids. At low lumenal choline concentrations, influx into colonic mucosa is slower than in jejunum and appears to be attributed solely to simple diffusion.

ie use of electrointraperitoneography in re-
ording digestive motility in different species of
imals is reported. An electrode with a diameter
150 μm is placed in a trocar and is inserted
ıto the abdominal muscles. In anesthetized rats,
ısic electrical rhythms (BER) were recorded most
equently in the jejunum, whereas in anesthetized
bbits, both BER and action potential spikes were
corded in the ileum. These types and sites of
tivity were also reported in conscious dogs.

'30 ACETYLSALICYLIC ACID AND GASTROINTESTINAL
PROPULSION IN THE RAT. (Eng.) Frenning,
.; Johansson, H.; Nilsson, F.; Ohrn, P. G.; Olazabal,
. (Univ. Hosp., S-750 14 Uppsala, Sweden). *Scand.*
Gastroenterol. 12(2):249-252; 1977.

ie possible influence of moderate amounts of acetyl-
alicylic acid (ASA) on gastric emptying, duodeno-
astric reflux, and small bowel propulsion was studied
Sprague-Dawley rats with permanent gastric and duo-
enal tubes. The ASA-containing or the control solu-
ion was introduced intragastrically 0.5 hr before the
imultaneous administration of radio-labeled test meals
ıto the stomach or duodenum. ASA was given as a 7.5
r 15.0 mM solution in 100 mM HCl or in 100 mM NaCl.
here were no significant differences in weight de-
elopment, gastric evacuation, or gastroduodenal reflux
etween the controls and any of the experimental groups.
n the control group that received 100 mM HCl, the small
owel length passed by 75, 50, and 25% of the test meal
uring 15 min was significantly less than in the group
iven 7.5 mM ASA in 100 mM HCl. Apart from this, there
ere no differences between the groups in small bowel
ropulsion. The results indicate that bile reflux or
elayed gastric evacuation have no role in the pathogenesis of the mucosal damage seen after therapeutic doses of ASA.

2731 RELAXATION OF THE LOWER OESOPHAGEAL SPHINCTER DURING SWALLOWING. (Eng.) Davison, J. S. (Dept. Physiology, The Univ., Dundee DD1-4HN, Scotland). *Digestion* 15(1):73-76; 1977.

A rapid pull-through technique was used to measure lower esophageal sphincter (LES) pressure before and immediately after swallowing in 10 subjects. In all subjects, under normal resting conditions, a distinct LES pressure profile was measured on every occasion during a pull-through. However, when the pull-through was carried out after a swallow, the recorded pressure usually changed from intragastric to intraesophageal with little or no intervening high pressure zone. In all such cases, powerful primary peristaltic waves were recorded a few seconds after the catheter had passed into the esophagus. The persistence of an attenuated profile was associated with relatively weakly developed peristalsis. In each subject, the mean LES pressure after a swallow was significantly lower than the mean control value. It is concluded that the reduction in recorded LES pressure is caused by sphincter relaxation following a swallow.

2732 STIMULATION OF LOWER ESOPHAGEAL SPHINCTER PRESSURE (LESP) BY CIMETIDINE--A DOUBLE-BLIND STUDY. (Eng.) Roesch, W.; Lux, G.; Schittenhelm, W.; Demling, L. (Medizinische Universitatsklinik, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepato-gastroenterol.* 23(6):423-425; 1976.

Using the rapid pull-through technique, the effect of p.o. administration of cimetidine on lower esophageal sphincter pressure (LESP) was studied in 14 volunteers. The subjects received in randomized order either two doses of 200 mg cimetidine or placebo in a double blind study. The integrated mean pressure was significantly higher following the administration of cimetidine (162.6 ± 67.3 mm Hg/min) than in controls (112.0 ± 40.3 mm Hg/min, $0.05>p>0.02$). In comparison with controls, the pentagastrin-stimulated (0.6 μg/kg) LESP was significantly higher ($p<0.05$) in the cimetidine-treated subjects. LESP was not affected by the infusion of atropine sulphate (25 μg/kg/hr) in either group. Cimetidine may stimulate LESP by blocking inhibitory gastrin receptors, such as somatostatin.

2733 EFFECT OF CIMETIDINE ON LOWER ESOPHAGEAL SPHINCTER PRESSURE, INTRAGASTRIC pH AND SERUM LEVELS OF IMMUNOREACTIVE GASTRIN IN MAN.

(Eng.) Siewert, R.; Lepsien, G.; Arnold, R.; Creutzfeldt, W. (Dept. General Surgery, Univ. Gottingen, Gosslerstrasse 10, 34 Gottingen, W. Germany). *Digestion* 15(1):81-85; 1977.

The influence of cimetidine on the lower esophageal sphincter (LES) pressure, the intragastric pH, and the serum levels of immunoreactive gastrin was investigated in eight healthy volunteers and the values were compared with those in eight controls. The LES pressure rose from 15.6 ± 1.1 to 22.7 ± 1.8 mm Hg ($p<0.05$) 20 min after the administration of cimetidine (400 mg, p.o.), and to 25.8 ± 2.0 mm Hg after 30 min ($p<0.001$). This pressure increase paralleled a rise in intragastric pH; the basal value was 1.7 ± 0.1, whereas the values 20, 60, and 120 min after cimetidine administration were 4.3 ± 0.9, 6.2 ± 0.4, and 4.25 ± 0.75, resp. In these subjects, the serum immunoreactive gastrin levels did not change. It is concluded that the rise in serum immunoreactive gastrin after the instillation of antacids into the stomach may be caused by distention of the antrum.

2734 THE MECHANISM OF ACTION OF GASTRIN ON THE LOWER ESOPHAGEAL SPHINCTER.

(Eng.) Rattan, S.; Coln, D.; Goyal, R. K. (Southwestern Medical Sch., Dallas, TX 75235). *Gastroenterology* 70(5):828-831; 1976.

The influence of atropine, metiamide, and tetrodotoxin on the effect of gastrin I or pentagastrin on lower esophageal sphincter pressure was studied in 29 opossums. Gastrin I (0.0075-10 μg/kg) or pentagastrin (2 μg/kg) caused contraction of the lower esophageal sphincter in anesthetized opossums. The contraction was not modified, either qualitatively or quantitatively, by 30 or 1,000 μg/kg atropine pretreatment. Moreover, neural block with tetrodotoxin (10-60 μg/kg, i.v.) did not influence the effect of gastrin on the sphincter pressure. Metiamide (2 mg/kg/hr or 10 mg/kg bolus, i.v.) did not modify the magnitude of the contractile response of the lower esophageal sphincter to gastrin I. These studies indicate that gastrin does not cause sphincter contraction by stimulating cholinergic neurons and that gastrin does not exert an inhibitory effect on the sphincter pressure by stimulating H_2 receptors. It is suggested that gastrin may contract the lower esophageal sphincter by a direct action of the sphincter muscle.

2735 ENDOGENOUS MOTILIN AND LOWER EXOPHAGEAL SPHINCTER PRESSURE IN MAN: CLUE TO AN ASSOCIATION.

(Eng.) Domschke, W.; Lux, G.; Mitznegg, P.; Rosch, W.; Domschke, S.; Bloom, S. R.; Wunsch, E.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-852 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 23(4):274-275; 1976.

The effects of endogenous motilin released by duodenal acidification on lower esophageal sphincter pressure (LESP) were studied in five healthy men. Three to four minutes after duodenal acidification by 0.1 N HCl (50 ml) instillation, the peak LESP was significantly elevated over the basal level by about 80% ($p<0.025$). This increase coincided with a rise in the plasma motilin level; the peak plasma motilin level exceeded the basal level by about 90% ($p<0.05$). The results indicate that motilin is involved in the intrinsic regulation of the lower esophageal sphincter.

2736 INTESTINAL TRANSIT IN RURAL AND URBAN POPULATION OF GREECE.

(Eng.) Manousos, O. N.; Nicolaou, A.; Zografos, A.; Trichopoulos, D.; Merikas, G. (Hippokration Hosp., Athens 610, Greece). *Digestion* 15(1):77-80; 1977.

Intestinal transit times and daily stool weights wer measured in 14 residents of Athens and 22 residents in rural Greece. The subjects in rural Greece had significantly shorter transit times (38.4 versus 56.8 hr, $p<0.02$) and heavier daily stools (172 versu 131 g, $p<0.05$) than those living in Athens. These findings may be attributable to the more refined die of the urban Greek population and may explain the different incidence of certain bowel diseases in the urban and rural Greek populations.

2737 ELECTRICAL SPIKE POTENTIALS OF THE SMALL BOWEL: A COMPARATIVE STUDY OF RECORDINGS OBTAINED FROM MUSCULAR IMPLANTED AND INTRALUMINAL SUCTION ELECTRODES.

(Eng.) Fleckenstein, P.; Oigaard, A. (Rigshospitalet, DK 2100 Copenhagen, Denmark). *Am. J. Dig. Dis.* 21(11):996-999; 1976.

Simultaneous spike potential recordings were obtaine in anesthetized dogs with intramuscular implanted electrodes, as well as intraluminal suction electrodes located on the same level. Number, amplitud duration, and time of onset of the potentials were compared from the two tracings to assess the reliability of intraluminal electrodes for clinical use The spike potentials from the intramuscular electro had a very similar appearance to those recorded fro intraluminal electrodes. However, the mean values for maximum and average action potential recorded b implanted electrodes (0.9 and 0.5 mV, resp.) were significantly higher than the corresponding figures from the suction electrodes (0.2 and 0.1 mV). Othe wise, the potentials were identical in number, duration, and time of onset. Thus, spike potentials recorded from suction electrodes, as used in clinical motility studies, accurately represent the eve within the muscular layer.

8 ACTION OF CAERULEIN, GLUCAGON OR PROSTA-
GLANDIN E_1 ON THE MOTILITY OF INTESTINAL
LI. (Eng.) Ihasz, M.; Koiss, I.; Nemeth, E. P.;
ly, G.; Papp, M. (Second Surgical Clinic, Semmel-
s Medical Univ., Budapest, Hungary). *Pfluegers*
h. 364(3):301-304; 1976.

kinetics of the effects of cerulein, glucagon,
prostaglandin E_1 on canine intestinal villous
ility were investigated. Cerulein (2.5-25 pg) in-
ased villous contraction in jejunal loops signifi-
tly ($p<0.01$). Jejunal motility also increased.
imilar response was observed with glucagon (125 ng-
g, $p<0.01$). Prostaglandin E_1 (250 ng/1 μg) signi-
antly decreased villous contractions ($p<0.01$).
relationship between the natural logarithm of the
g doses and their effect was linear in all three
es.

9 THE MODULATION OF THE PROSTAGLANDIN-
INDUCED (E_1, E_2, $F_{2\alpha}$) MOTILITY OF THE LARGE
ESTINE BY THE ADRENERGIC SYSTEM. (Eng.) Bruch,
P.; Schmidt, E.; Laven, R. (Dept. Surgery, Univ.
zburg, Josef-Schneider-Str. 2, D-8700 Wurzburg,
Germany). *Acta Hepatogastroenterol.* 23(6):430-
; 1976.

colonic motility is produced by the interaction
the cholinergic parasympathetic and the adrenergic
pathetic systems, the effects of adrenergic stim-
tors and inhibitors on prostaglandin-stimulated
onic motility were studied in 20 human taenia
i strips. Prostaglandin (10^{-4}-1 μg/ml)-induced
tractions were unaffected by α- and β-receptor
agonists. Contractions produced by 1 μg/ml pros-
landin were completely eliminated by adrenalin
μg/ml), noradrenalin (1 μg/ml), and isoproterenol
x 10^{-1}-10 μg/ml). β-Blockade with propranolol
μg/ml) and the addition of adrenalin or noradren-
n resulted in a 200% increase in prostaglandin-
uced tension. The increase in prostaglandin-
uced contraction by catecholamines and β blockade
neutralized by the α-receptor antagonist phentol-
ne (1 μg/ml). The results indicate the presence
α-receptors in the human large intestine.

0 THE MOTOR-STIMULATING EFFECT OF RECTALLY
ADMINISTERED METOCLOPRAMIDE ON THE HUMAN
DENUM. (Eng.) Fleckenstein, P.; Oigaard, A.;
ph, S. (Rigshospitalet, Blegdamsvej 9, DK-2100
enhagen O, Denmark). *Dan. Med. Bull.* 23(6):300-
; 1976.

denal motility was studied before and after the
tal administration of metoclopramide (40 mg) in
healthy volunteers, and the results were compared
those obtained previously in 20 subjects who re-
ved the same dose i.v. A comparison of cumula-
e sum charts of duodenal activity after both
tes of administration revealed that the motor-
mulating effect after i.v. administration occurred
ost immediately, whereas the stimulation after
tal administration was delayed by about 15 min
-23 min). However, the effect was of the same
ler of magnitude during the observation period,
indicated by the identical linear gradient of the
two curves. The results indicate that biologically active quantities of metoclopramide are absorbed from the human rectum.

2741 PHARMACOLOGICAL ANALYSIS OF PERISTALSIS OF THE ISOLATED GUINEA PIG ILEUM BY TETRAMETHYLAMMONIUM. (Fre.) Beleslin, D.; Samardzic, R.; Malobabic, Z. (Institut de Pharmacologie, Faculte de Medecine, 11000 Beograd, C.P. 662, Yugoslavia). *C. R. Soc. Biol. (Paris)* 170(2):331-335; 1976.

Pharmacological analysis of the inhibition of tetramethylammonium (TT)-induced peristalsis of the isolated guinea pig ileum was examined. At low concentrations, TT (5 μg/ml) contracted the longitudinal muscle, but it only blocked the peristaltic reflex at higher doses (25 μg/ml). Acetylcholine (30-60 μg/ml), methacholine (5-30 μg/ml), and carbachol (0.05-0.15 μg/ml) reversed the TT-induced block. Propionylcholine and butyrylcholine (50-500 μg/ml) could not reverse the block in the presence of TT, although they did contract the longitudinal musculature. Eserine (0.005-0.015 μg/ml) and neostigmine (0.005-0.2 μg/ml) reversed the TT-induced block and produced regular peristaltic waves after some latency. Nicotine (25-100 μg/ml), pilocarpine (2-10 μg/ml), 5-hydroxytryptamine (0.5-10.0 μg/ml), arecoline (0.015-0.03 μg/ml), and histamine (1-20.0 μg/ml) did not reverse the TT-induced block. The cholinoceptive ganglia of the myenteric plexus appears to be the predominant site of the depressive effect of TT.

2742 THE PARTICIPATION OF ENTERIC INHIBITORY NERVES IN ACCOMMODATION OF THE INTESTINE TO DISTENSION. (Eng.) Furness, J. B.; Costa, M. (Flinders Univ. of South Australia, Bedford Park, South Australia 5042, Australia). *Clin. Exp. Pharmacol. Physiol.* 4(1):37-41; 1977.

To test the hypothesis that the enteric inhibitory nerves participate in the accomodation of the intestine to distension, experiments were carried out on isolated segments from the distal colon of the guinea pig. When a weight was applied to the colon in a control solution, the wall distended very quickly at first, then distended more slowly over the 20 sec before the weight was removed. In the presence of tetrodotoxin (10^{-7} g/ml), the second, slow phase of distension was usually abolished, and the circular muscle sometimes contracted back towards its original length during this period. The resting length of the circular muscle did not change when tetrodotoxin was added to the organ bath. Tetrodotoxin reduced the distensibility of the colon to about half when compared with the control, but other drugs (i.e., bretylium, 10^{-6} g/ml; guanethidine, 10^{-6} g/ml; hyoscine, 6 x 10^{-7} g/ml; or methysergide, 10^{-6} g/ml) had no significant effect. It is concluded that a local reflex involving enteric inhibitory nerves causes an accommodation of the intestine to stretch.

2743 EFFECT OF PROSTAGLANDIN E_1 ON RAT GASTRIC MOTILITY AND CYCLIC NUCLEOTIDE CONTENT. (Eng.) Shearin, N. L.; Pancoe, W. L.

(Faculty Medicine, Memorial Univ. Newfoundland, P.O. Box 129, St. John's, Newfoundland A1C 5S7, Canada). *Experientia* 32(12):1553-1554; 1976.

The effect of prostaglandin E_1 (PGE_1) on gastric motility and cyclic nucleotide content was studied *in vivo* in male Holtzman rats. Five rats received daily i.p. injections of PGE_1 (4.5 mg/kg). A telemetry system was used to monitor stomach motility. The mean motility index in the treated rats was significantly higher than that in controls (84 ± 8.20 versus 61 ± 16.10, $p<0.05$). The cyclic AMP concentration in the PGE_1-treated animals (5 ± 1.20 pmol/g tissue) was significantly lower than that in controls (16 ± 1.40 pmol/g, $p<0.05$), and the cyclic guanosine monophosphate level was significantly higher in the treated animals (0.45 ± 0.03 versus 0.30 ± 0.20 pmol/g). It is concluded that the administration of PGE_1 influences total fundic tissue levels of the two cyclic nucleotides and serves as a positive feedback on cholinergic activity. The increase or decrease in contractile activity is affected by the interaction between exogenous PGE_1, cyclic AMP, and cyclic guanosine monophosphate and is controlled by significant decreases in the tissue levels of these two cyclic nucleotides.

2744 EFFECT OF TRYPTOPHAN AND ITS METABOLITES ON GASTRIC EMPTYING OF LIQUID MEALS IN DOGS. (Eng.) Cooke, A. R.; Ward, W. O. (Veterans Admin. Hosp., Iowa City IA 52240). *Proc. Soc. Exp. Biol. Med.* 152(4):656-658; 1976.

The effects of tryptophan and its metabolites were studied in five dogs with chronic gastric fistulas to determine whether the known inhibiting effect of trytophan on emptying is due to local or systemic effects or to trytophan metabolites. The instillation of 300 ml of DL-kynurenine (5 mM), 5-hydroxytryptophan (5 mM), or 5-hydroxytryptamine (20 mM) into the gut did not slow gastric emptying. Furthermore, the i.v. infusion of L-tryptophan (5, 20, and 50 mM), DL-kynurenine (2, 5, and 10 mM), 5-hydroxytryptamine (2 and 10 mM), and 3-indolepyruvic acid (2, 5, and 10 mM) failed to slow gastric emptying. The results indicate that tryptophan slows gastric emptying by exciting a receptor in the gut and not by a direct effect on the stomach or brain or via its major metabolites.

2745 ELECTROMYOGRAPHY OF THE SPHINCTER OF ODDI IN THE RABBIT. II. EFFECT OF VAGOTOMY, HEXAMETHONIUM AND ALCOHOL. (Fre.) Sarles, J. C.; Midejean, A.; Devaux, M. A.; Gastagnini, A. (Service de Chirurgie, C.H.U., Hopital d'Aubagne, avenue de Petit-Canedel, F 13667 Aubagne, France). *Biol. Gastroenterol. (Paris)* 9(1):25-32; 1976.

The effects of vagotomy, hexamethonium bromide (1-2 mg/kg/hr, i.v.), or *in vitro* or i.v. alcohol (1 g/kg) on the sphincter of Oddi were studied in rabbits. Hexamethonium decreased electrical activity and biliary pressure. *In vitro* alcohol had no effect on the sphincter, however the slow i.v. infusion of alcohol caused increased electrical activity. Vagotomy provoked a transient depression (30-60 min) of the electrical activity and greatly decreased the effect of alcohol. I.v. hexamethonium (2 mg/kg/hr) completel eliminated the stimulating effect of alcohol. Alcohol apparently acts upon the sphincter of Oddi through a nerve pathway that includes the vagus nerve.

2746 A SPECIAL CLOSURE SYSTEM OF THE GASTROINTESTINAL TRACT OF THE RAT. AN EXPERIMENTAL STUDY OF THE STRUCTURE AND FUNCTION OF A GASTROINTESTINAL CLOSURE SYSTEM. (Ger.) SECRETION AND METABOLISM

2772 IN VITRO BIOTRANSFORMATION OF OLEIC ACID (I-^{14}C) IN RABBIT CECAL CONTENTS. ROLE OF MICROFLORA AND EXOCRINE PANCREATIC SECRETION. (Fre.) Perret, J. P. (Institut Universitaire de Technologie, Laboratoire de Physiologie, 43, boulevard du 11-Novembre-1918, 69 Villourbanne, France). *Ann. Biol. Anim. Biochim. Biophys.* 16(1):71-84; 1976.

The effect of prior deprivation of pancreatic excretion on the ability of the cecal contents of rabbits to metabolize oleic acid was studied. Some cecal samples were cleared of microorganisms by filtration before incubation with the ^{14}C-labeled oleic acid. Optimal pH was found to be 6-7 (0.05 M phosphate). Six weeks prior to sacrifice for removal of cecal contents, three of six rabbits were subjected to ligature of the main pancreatic duct. Contents from the three control rabbits esterified 22.7-30% of the oleic acid (to phospholipids, sterol esters, methyl ester) in 4-8 hr and hydrogenated 60% of esterified compounds in 8 hr. Operated rabbits had cecal samples that esterified not more than 5% of the oleic acid and hydrogenated only 7%. Oleic acid biotransformation did not occur in the absence of microorganisms. Addition of pancreatic juice to cecal contents of pancreatic secretion-deprived rabbits reestablished esterification to 33%, but hydrogenation remained below control levels.

2773 AUTORADIOGRAPHIC STYDY WITH ^{14}C-LABELLED PENTAGASTRIN IN THE RAT. (Eng.) Varkonyi, T.; Varga, L.; Nafradi, J.; Kozma, M.; Kasa, P.; Varro, V. (Univ. Medical Sch., H-6701, Szeged, Hungary). *Acta Hepatogastroenterol.* 23(6):426-429; 1976.

The metabolism and elimination of ^{14}C-glycine-labeled pentagastrin were studied autoradiographically and by light microscopy in Wistar rats. Twenty-one animals received 500 μg of ^{14}C-glycine-labeled pentagastrin i.v. As early as 10 sec after the injection, activity was observed in the liver and in association with the parietal cells of the gastric mucosa. The radioactivity remained in the liver for a prolonged period (>6 min), while it had disappeared from the parietal cells by 2 min after injection. Activity was detected in the renal tubuli 2 min or more after pentagastrin administration. The highest grain densit
was observed in the liver tissue.

SECRETION AND METABOLISM

Stomach

781 LATERAL HYPOTHALAMIC "FEEDING" SITES AND GASTRIC ACID SECRETION. (Eng.) Wyrwicka, . (Veterans Admin. Wadsworth Hosp. Center, Los ngeles, CA 90024). *Experientia* 32(10):1287-1289; 976.

o determine whether the lateral hypothalamic strucures that govern the initiation of feeding also inluence gastric acid secretion, experiments were caried out in gastric fistula cats in which feeding was voked by electrical stimulation of the lateral hypohalamus. Electrical stimulation that had been efective in evoking stimulus-bound feeding in satiated ats did not produce any significant stimulating efect on gastric acid secretion in the same cats when hey were hungry ($p>0.05$). The results are not conistent with those previously reported in which gasric acid secretion increased in response to electrial stimulation.

782 COBALAMIN BINDING PROTEINS IN STOMACH AND SERUM FROM VARIOUS ANIMAL SPECIES DATA FOR $_{12}$ BINDING CAPACITIES AND MOLECULAR SIZES OF THE INDING PROTEINS. (Eng.) Hippe, E.; Jorgensen, . S.; Olesen, H. (Bispebjerg Hosp., Glostrup, Denark). *Comp. Biochem. Physiol.* [*B*] 56(3B):305-309; 977.

he cobalamin-binding capacity of stomach mucosa nd serum from 38 animal species, including man, ere determined, and the size of binding in terms f Stokes radius and estimated molecular mass was easured. The binding capacity for exogenous cobalamin varied from 0.75 nmol/kg (lugworm) to 570 nmol/g (pig). In the serum, the capacity was 0.4 nM (ferret) to 270 nM (grass snake). The cobalamin-inding capacity of serum was not correlated to the erum cobalamin concentration in the various species, xcept for the nine fish species (hagfish, lamprey, spiny dogfish, eel, plaice, ray, starry rat, sea trout, and cod); in these species, the correlation coefficient was 0.65 ($p<0.05$). The Stokes radius f the cobalamin-binding proteins varied from 1 to nm both in the mucosa and in serum. In the mamals, it was 2.5 to 5.5 nm; in humans, the binders had relative molecular weights of 35,000 or 50,000-60,000.

2783 RENAL EXTRACTION OF ENDOGENOUS GASTRIN IN PATIENTS WITH NORMAL RENAL FUNCTION. (Eng.) Schjonsby, H.; Willassen, Y. (Medical Dept. A, Univ. Bergen, 5016 Haukeland Hosp., Bergen, Norway). *Scand. J. Gastroenterol.* 12(2):205-207; 1977.

Renal gastrin excretion was assessed in 23 subjects by measuring gastrin levels in the brachial artery and the renal vein. There was no significant difference in arterial gastrin (37.7 ± 25.1 pg/ml serum) and the renal vein gastrin (35.9 ± 24.6 pg/ml) in the fasting subjects, resulting in a renal extraction ratio for gastrin not significantly different from zero ($p>0.5$). Among three patients who had consumed a protein-rich meal, two showed no gastrin extraction during two consecutive periods, while the third showed a gastrin extraction of 0.12 in the second period. The cause of hypergastrinemia in renal failure is still uncertain, but could be due either to increased gastrin production or to decreased elimination. The results, however, do not support the hypothesis that hypergastrinemia is due to decreased elimination by the kidney.

2784 GASTRIN, ANTRAL G CELLS, AND GASTRIC ACID IN SECRETAGOGUE-INDUCED AND ANTIHISTAMINE-INHIBITED DUODENAL ULCERS. (Eng.) Joffe, S. N.; Polak, J. M.; Pallone, F.; Bloom, S. R.; Gaskin, R. J.; Barros D'Sa, A. A. J.; Baron, J. H. (Royal Infirmary, Glasgow, G4 OSF, Scotland). *Scand. J. Gastroenterol.* 12(1):27-32; 1977.

The effects of the antihistamine derivative Pfizer UK-9040 on basal and secretagogue-stimulated gastric secretion, plasma and antral G cell gastrin levels, and ulcerogenesis in fasted Wistar albino rats were investigated. Control and operated (pylorus ligated and catheter inserted) rats were divided into four treatment groups receiving: s.c. saline, oral pretreatment with UK-9040 (100 mg/kg) followed by s.c. saline, s.c. infusion of ulcerogenic levels of the secretagogues pentagastrin (4 μg/kg/min) and carbachol (0.8 μg/kg/min), and oral pretreatment with UK-9040 (100 mg/kg) followed by an s.c. infusion of pentagastrin (4 μg/kg/min) and carbachol (0.8 μg/kg/min). Hypergastric secretion induced by secretagogues was inhibited 58% by pretreatment with UK-9040, although maximal secretion at 6 hr was still elevated four times over that in controls. UK-9040 elevated levels of total plasma gastrin from 6.9 ± 1.2 to 39.7 ± 8.5 fm/ml ($p<0.001$) at 24 hr. Secretagogue infusion produced no elevation of plasma gastrin, and reduced the stimulatory effects of UK-9040. Control and secretagogue-treated rats were found to have normal levels of antral G cell gastrin, while UK-9040 treatment markedly reduced gastrin content and cell size. Duodenal ulcers were found in all of the secretagogue-treated rats, but in only one-third of the rats treated with UK-9040 and secretagogue. It was concluded that UK-9040 directly inhibits gastric parietal cell acid secretion, while directly or indirectly stimulating release of gastrin from antral G cells, causing the elevation of plasma gastrin.

2785 EFFECTS OF COMMON INHIBITORS OF GASTRIC ACID SECRETION ON SECRETAGOGUE-INDUCED RESPIRATION AND AMINOPYRINE ACCUMULATION IN ISOLATED GASTRIC GLANDS.

(Eng.) Berglindh, T. (Biomedical Center, Univ. Uppsala, Uppsala, Sweden). *Biochim. Biophys. Acta* 464:217-233; 1977.

The effects of three inhibitors of gastric acid secretion were studied in isolated glands from the rabbit gastric mucosa. The glands were either resting or stimulated by carbachol, histamine, or dibutyryl cyclic AMP. The effects were determined from changes in oxygen consumption and accumulation of aminopyrine. Atropine (10^{-6} M) almost totally inhibited the transient response induced by carbachol (10^{-4} M) in both measured parameters. The histamine-induced increase in respiration was inhibited when the atropine concentration was raised to 10^{-4} M. To a lesser extent, histamine-induced aminopyrine accumulation was reduced. The dibutyryl cyclic AMP-stimulated oxygen consumption was not affected by atropine. Burimamide (2.4×10^{-5} M) competitively inhibited the histamine responses, but had no effect on those of carbachol and dibutyryl cyclic AMP. Thiocyanate (10^{-2} M) inhibited the increase in oxygen consumption induced by all three secretagogues, but not to the prestimulatory level, in spite of a total abolishment of the aminopyrine accumulation. In unstimulated glands, burimamide (10^{-3} M) or atropine (10^{-4} M) did not alter the normal aminopyrine ratio (aminopyrine in intraglandular water/aminopyrine in extraglandular water) of approximately 50. This may indicate the existence of preformed acid in resting parietal cells. Thiocyanate, on the other hand, lowered the aminopyrine ratio in unstimulated glands from 46 to 2. The thiocyanate effect may be due to an inability to separate acid and base in the secreting membrane.

2786 EFFECTS OF ACETYLSALICYLATE ON ALKALINIZATION, ACID SECRETION AND ELECTROGENIC PROPERTIES IN THE ISOLATED GASTRIC MUCOSA.

(Eng.) Garner, A. (Biomedical Centre, Univ. Uppsala, Uppsala, Sweden). *Acta Physiol. Scand.* 99(3):281-291; 1977.

The effects of acetylsalicylate (ASA) on the *in vitro* secretory and electrical properties of *Necturus* and *Rana temporaria* gastric mucosa were studied to further examine the mechanisms by which salicylates affect gastric secretion and produce gastric damage. Metiamide was used to inhibit acid secretion for studies on fundic alkalinization in *Rana temporaria*. Submucosal application of 3 mM ASA for 30 min markedly reduced alkalinization in the antrum and the frog fundus. Following removal of ASA, there was only partial recovery of this secretion. The drug caused slight inhibition of spontaneous acid secretion in *Necturus* fundus, but not of histamine-stimulated acid secretion in the frog fundus. Following salicylate removal, the rate of acid secretion increased to a higher level than before administration in both tissues. There was a small flux of ASA across the mucosa, which was greatest in the acid secreting frog fundus (4.38 μmol/cm/min) and least in the antrum (2.19 μmol/cm/min). Exposure of the gastric mucosa to ASA was generally associated with a fall in transmucosal electric potential difference and short-circuit current, together with an increase in electrical resistance. The greater sensitivity of alkalinization to ASA may be responsible for the apparent increase in the rate of acid secretion.

2787 KINETICS OF ATROPINE INHIBITION OF PENTAGASTRIN-STIMULATED H^+, ELECTROLYTE, AND PEPSIN SECRETION IN THE DOG.

(Eng.) Hirschowitz, B. I.; Hutchison, G. A. (Dept. Medicine Univ. Alabama in Birmingham, Birmingham, AL 35294). *Am. J. Dig. Dis.* 22(2):99-107; 1977.

The effects of atropine on pentagastrin-stimulated gastric secretion of water, acid, electrolyte, and pepsin were determined by kinetic analysis of dose-response studies in five dogs with esophagostomy and gastric cannula. Dogs received seven separate doses of pentagastrin (1-6 μg/kg/hr, i.v. for 4 hr). The same series of doses was used with atropine sulfate (10 μg/kg/hr) as background. Atropine inhibited pentagastrin-stimulated secretion competitively, with a dose ratio change of 20. In a third set of studies, pentagastrin was infused alone for 4 hr (1.5 μg/kg/hr) and then with each of seven doses of atropine (0.625-40 μg/kg/hr), each dose used separately. Atropine competitively inhibited water, H^+, Cl^-, and K^+ secretion, with K_i (dose of atropine giving 50% inhibition) of 1.0 μg/kg/hr. Pepsin secretion was much more strongly inhibited than acid secretion by atropine, with a K_i of 0.27 μg/kg/hr, and the inhibition was uncompetitive. The calculated maximal inhibition of H^+ secretion by atropine was 89% and of pepsin, 95%. The shape of the response curve to pentagastrin was altered by atropine so that the peak response was delayed to the third and fourth hour of pentagastrin infusion. These studies suggest that atropine has a much more direct effect on pentagastrin-stimulated secretion than on histamine-stimulated secretion in the dog.

788 THE EFFECT OF PORCINE CALCITONIN UPON GASTRIC ACID SECRETION AND SERUM GASTRIN IN

AN. (Eng.) Pedersen, L.; Thaysen, E. H. (Aalborg
ygehus Nord, Aalborg, Denmark). *Scand J. Gastro-*
terol. 11(Suppl. 42):43-47; 1976.

e inhibitory action of porcine calcitonin on gas-
ic acid secretion was studied in three healthy men
d a 56-yr-old woman with the Zollinger-Ellison syn-
ome. Gastric acid secretion in the healthy subjects
s stimulated by pentagastrin (1 μg/kg/hr, 150 min).
lcitonin infusion (1 MRC U/kg/hr) in all subjects
used a prompt decrease in gastric acid output.
lcitonin infusion caused no changes in serum calcium
phosphate levels in any subject, although the serum
strin level increased in one of the healthy subjects.
en acid secretion was stimulated by histamine (40
/kg/hr, 150 min) in the three healthy subjects, cal-
tonin again suppressed gastric acid output, but to a
sser extent than during pentagastrin stimulation.
lcitonin may be useful in the pre- and peroperative
nagement of patients with the Zollinger-Ellison syn-
ome, and perhaps in the treatment of patients with
ife-threatening bleeding from erosive gastritis.

789 EFFECTS OF CIMETIDINE AND ATROPINE SULFATE ON GASTRIC SECRETION AND HEALING OF GAS-

RIC AND DUODENAL ULCERS IN RATS. (Eng.) Okabe,
.; Takeuchi, K.; Murata, T.; Takagi, K. (Dept.
emical Pharmacology, Univ. Tokyo, Hongo, Bunkyo,
okyo, Japan). *Eur. J. Pharmacol.* 41(2):205-208;
977.

e effects of cimetidine on gastric secretion and
lcer healing were compared to those of atropine
lfate in male Donryu rats. The intraduodenal ad-
inistration of cimetidine (50 or 100 mg/kg) in two
ivided doses after pylorus ligation inhibited gas-
ric acid secretion by 60.7% and 83.7% ($p<0.001$ in
oth cases) at the respective doses and inhibited
he pepsin output by 35.9% and 60.4% ($p<0.05$ and
<0.001, resp.). Atropine sulfate (15 mg/kg) also
ignificantly reduced acid and pepsin output (96.1%
nd 87.0%, resp.). At 12.5 mg/kg, cimetidine pro-
uced no significant reductions in acid or pepsin
utput. The administration of cimetidine by gas-
ric tube for 12 consecutive days significantly
mproved the healing index of experimentally in-
uced gastric ulcers by 17.7% at 100 mg/kg/day
$p<0.05$) and by 40.8% at 200 mg/kg/day ($p<0.01$).
he administration of the same doses for 10 consecu-
ive days improved experimental duodenal ulcers by
4.4% ($p<0.001$) and 41.6% ($p<0.01$), resp. The ad-
inistration of atropine sulfate (30 mg/kg/day) for
he same time periods did not significantly improve
he healing index of gastric ulcers, but did im-
rove the healing of duodenal ulcers by 38.8%
$p<0.001$). The results suggest that the enhance-
ent of ulcer healing by cimetidine is a result of
ts ability to suppress gastric secretion.

790 EFFECTS OF CIMETIDINE ON ADENYLATE CYCLASE ACTIVITY OF GUINEA PIG GASTRIC MUCOSA

TIMULATED BY HISTAMINE, SODIUM FLUORIDE AND 5'-
UANYLYLIMIDODIPHOSPHATE. (Eng.) Anttila, P.; Westermann, E. (Institut fur Pharmakologie der Medizinischen Hochschule Hannover, Karl Wiechert-Allee 9, D-3000 Hannover 61, W. Germany). *Naunyn-Schmiedeberg's Arch. Pharmacol.* 294(2):209-211; 1976.

To investigate the mode of action of cimetidine, the modification of the stimulatory effects of histamine, sodium fluoride, and 5'-guanylylimidodiphosphate by cimetidine on the adenylate cyclase activity of guinea pig gastric mucosa was studied. The effect of cimetidine was compared with that of metiamide. Cimetidine (10^{-6}-10^{-4} M) inhibited histamine stimulated (10-100 μM) adenylate cyclase activity *in vitro* in a dose-dependent manner. NaF- and 5'-guanylylimidodiphosphate-stimulated activity was not affected by cimetidine. Cimetidine was about 10-fold more potent than metiamide in inhibiting the histamine-stimulated adenylate cyclase activity in the guinea pig gastric mucosa. The results demonstrate that the effect of cimetidine is qualitatively, but not quantitatively, similar to that of metiamide.

2791 THE EFFECT OF CIMETIDINE ON MEAL-STIMULATED GASTRIC FUNCTIONS MEASURED WITH A NEW METHOD.

(Eng.) Moberg, S.; Carlberger, G.; Gilljam, H.; Befritz, R. (St. Goran's Hosp., P.O. Box 12500, S-112 81 Stockholm, Sweden). *Scand. J. Gastroenterol.* 12(2):145-148; 1977.

A new method for the measurement of meal-stimulated acid secretion, gastric emptying, and the amount of hydrogen ions delivered to the duodenum is presented in which bicarbonate infusion is unnecessary. This method was used to determine the effect of cimetidine on meal-stimulated gastric functions in six healthy subjects. The subjects received a 300-ml fluid test meal that did not change the pH of the stomach contents; 66 min later, a control i.v. infusion with saline was replaced with cimetidine (100 mg/hr, 30 min). Although gastric emptying was not affected by cimetidine, gastric acid secretion was markedly reduced. Determination of meal-stimulated gastric secretion may give a better physiological measure of gastric function than that of drug stimulation, and eliminating the need for bicarbonate infusion with meal-stimulated acid stimulation prevents the interference of bicarbonate with the liberation of antral gastrin. However, a limitation of the new method is that the meal must be homogeneous in the stomach, and the regurgitation of alkaline duodenal contents and back-diffusion of hydrogen ions through the stomach wall cannot be accounted for.

2792 GLUCOCORTICOID AND MINERALOCORTICOID ACTIONS ON GASTRIC SECRETION IN MAN.

(Eng.) Domschke, W.; Domschke, S.; Huber, W.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 24(1):34-37; 1977.

The effects of glucocorticoids and mineralocorticoids on gastric secretion were studied in 22 women without upper gastrointestinal disease. Twelve subjects received prednisolone (1 g/day, i.v.) for 6 consecutive days. The 10 remaining subjects received 9-alpha-fluorohydrocortisone (0.3 mg/day, p.o.) for 6 days. The 12 subjects receiving prednisolone subsequently received 9-alpha-fluorohydrocortisone for 9 days and prednisolone during days 4-9. None of the treatment regimens produced any significant changes in gastric acid, protein, or pepsin secretion. Following prednisolone treatment, the secretion of N-acetylneuraminic acid (NANA) bound to glycoproteins (5.9 ± 3.2 μmol/hr) was decreased, in comparison with the level before treatment (9.4 ± 3.7 μmol/hr). This effect was not prevented by concomitant mineralocorticoid treatment. Gastroduodenoscopy revealed no lesions attributable to drug administration. The data do not reveal any beneficial effects of mineralocorticoids in the treatment of peptic ulceration.

2793 EFFECT OF AN INHIBITOR OF PEPSIN PROTEOLYTIC ACTIVITY IN THE EXALTO-MANN-WILLIAMSON ULCER. (Eng.) Alphin, R. S.; Droppleman, D. A. (A. H. Robins Res. Lab., Dept. Pharmacology, Richmond, VA 23220). *Eur. J. Pharmacol.* 41(2):235-237; 1977.

The effect of the pepsin inhibitor, lignosulfonate, on the Exalto-Mann-Williamson ulcer model in the dog was studied. In untreated controls, the incidence of jejunal ulcers after this procedure was 92% (12/13 animals). Eight of the 12 affected animals had jejunal perforation at the time of death, which ranged from 26-46 days. Body weight losses ranged from 20-46%. Although survival time, weight loss and hemoglobin and hematocrit decreases were similar in lignosulfonate-treated (500 mg/2 hr, p.o.) dogs, only four of the nine treated animals had pathological changes in the jejunum. Two of the four had perforated ulcers. These studies demonstrate that pepsin plays an important role in the Exalto-Mann-Williamson ulcer.

2794 INHIBITION OF GASTRIC SECRETION BY COMBINED SECRETIN AND CCK AND COMBINED GLUCAGON AND CCK. (Eng.) Hendel, L.; Henriksen, F. W. (Kobenhavns Amtssygehus in Glostrup, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 42):37-39; 1976.

Because secretin, glucagon, and cholecystokinin (CCK) are likely to be released simultaneously under physiological conditions, possible interactions in their inhibitory effect on gastric secretion were investigated. After a basal period of 30 min, gastric secretion in 19 subjects was stimulated by a continuous infusion of pentagastrin (0.15, 1.0, and 6.0 μg/kg/hr) for 2 hr. After 1 hr, secretin, CCK, or a combination of the two was superimposed. In some experiments, glucagon and CCK were infused simultaneously. The inhibitory effects of secretin or CCK on gastric fluid secretion were not enhanced when the two were infused simultaneously. However, the inhibitory effect of secretin in low doses (0.5 clinical U/kg/hr) on gastric acid secretion was augmented by the simultaneous infusion of low doses of CCK (0.5 Ivy dog U/kg/hr). CCK did not augment the inhibitory effect of glucagon.

2795 LONG-TERM EFFECTS OF HIGHLY SELECTIVE VAGOTOMY (HSV) IN DOGS ON ACID AND PEPSIN SECRETION. (Eng.) Hirschowitz, B. I.; Hutchison, G. A. (Medical Center, Univ. Alabama in Birmingham, University Station, Birmingham, AL 35294). *Am. J. Dig. Dis.* 22(2):81-95; 1977.

Gastric acid and pepsin secretion studies before and for 40 months after fundic vagotomy (HSV) in three fistula dogs were carried out with the vagal stimula 2-deoxyglucose (2-DG), and dose responses to urecholine, histamine, and pentagastrin were determined. Initially HSV completely blocked the secretory response to 2-DG, but secretion began to recover by 5- months, and from 16 months on, secretion stabilized at 60% gastric acid and 13-17% pepsin (preoperative=100%). After HSV, the stomach was hypersensitive t urecholine, with a lower threshold and lower K_m, but unchanged V_m, while with histamine, the curves were shifted to the right, with V_m unchanged and K_m increased. With pentagastrin, there was also a small decrease in V_m. Pepsin responses to urecholine recovered and exceeded control by 16 months, but remained relatively unresponsive to histamine or pentagastrin. A cholinergic background provided by urecholine at subthreshold doses (<10 μg/kg/hr) restore both pentagastrin and histamine responses to prevagotomy levels. Gastrin release from the innervated antrum by 2-DG was greater than in controls and was atropine sensitive. The results indicate that denervation of the secretory mucosa, especially of the peptic cells, is never more than partially reversed even after 3 yr. Even though the response to vagal stimulation is partial, the mucosa remains capable normal response, i.e., there is no atropy, and the vagus is not directly trophic to the gastric fundus Moreover, vagotomy was followed by some hypersensitivity to urecholine, indicating changes in cholinergic receptors like those seen in denervated muscl cells.

2796 ON THE LOCATION OF GASTRIC DIGESTION. (Rus.) Ivashkin, V. T.; Dorofeyev, G. I. (S. M. Kirov Military Medical Acad., Leningrad, USSR). *Vrach. Delo* (4):117-121; 1976.

SECRETION AND METABOLISM

Pancreas

833 EXPERIMENTAL STUDIES ON THE SCINTIGRAPHY OF THE PANCREAS IN RATS AND DOGS BY USING SOTOPE LABELLED DYE. (Eng.) Bando, A. (Kobe Univ. ch. Medicine, Kobe, Japan). *Kobe J. Med. Sci.* 2(2):47-62; 1976.

ne use of isotope-labeled tetraiodo-dye solutions n scintigraphy of the pancreas was investigated in ats and dogs. Eight percent erythrosin B solution % EB), ^{131}I-erythrosin B (^{131}I-EB), and ^{131}I-rose engal solution (^{131}I-RB) were administered i.v., i.p., r i.m. to rats and dogs. Uptake of the solutions in ne pancreas, liver, heart, spleen, lungs, kidneys, and nyroid was observed at various intervals for a 24- r period. The effects of esberiven, a lymph flow ccelerator, and gascon, a surfactant, upon intra- eritoneally administered ^{131}I-RB were also ob- erved. Eight percent ^{131}I-EB was found to be apidly absorbed by the pancreas, creating only a odest peak after 5 min and was excreted into the uodenum within 30 min of i.v. injection. The reatest and most selective uptake of the pancreas as obtained after i.p. injection of ^{131}I-EB and ^{31}I-RB, with the intrapancreatic concentration ex- eeding the intrahepatic concentration by a factor f 5-9, and 10, resp., only 5 min after injection. urthermore, the dyes were retained in the organs or over 60 min. Intraperitoneally administered sberiven plus ^{131}I-RB significantly increased dye ptake by the pancreas (100-200%), as well as ac- elerating the rate of uptake. Gascon accelerated ye uptake and excretion more than esberiven, but ye uptake was decreased by about 50%. The pan- reatic concentrations yielded by use of ^{131}I-RB i.p.) were four to six times higher than those roduced by the present method of i.v. administra- ion of ^{75}Se-selenomethionine.

834 DISCHARGE OF NEWLY SYNTHESIZED PROTEINS IN PURE JUICE COLLECTED FROM THE HUMAN ANCREAS: INDICATION OF MORE THAN ONE POOL OF INTRA- ELLULAR DIGESTIVE ENZYMES. (Eng.) Robberecht, P.; remer, M.; Christophe, J. (Free Univ. Brussels Med- cal Sch., Waterloo Blvd. 115, B-1000 Brussels, Bel- ium). *Gastroenterology* 72(3):417-420; 1977.

he total output of pancreatic proteins in man was ompared with the secretion of newly synthesized pro- eins. The pancreatic secretion of six normal vol- nteers was collected by endoscopic cannulation of he main pancreatic duct. The appearance of newly synthesized proteins was monitored at 1-min intervals after labeling with ^{75}Se-methionine. The minimum transit time of these proteins from their site of synthesis to the acinar lumen was 36 ± 8 min. Stimulation of protein secretion by a rapid i.v. injection of cerulein (40 ng/kg) 1 hr after ^{75}Se-methionine administration, decreased the specific radioactivity of the discharged proteins by an average of 73%. These data support the concept of a functional heterogeneity of proteins secreted by the human pancreas.

2835 STUDIES ON SECRETORY GLYCOPROTEINS IN THE RAT EXOCRINE PANCREAS. I. FINE STRUCTURE OF THE GOLGI COMPLEX AND RELEASE OF FUCOSE-LABELED PROTEINS AFTER IN VIVO STIMULATION WITH CAERULEIN. (Eng.) Volkl, A.; Bieger, W.; Kern, H. F. (Dept. Anatomy, Univ. Heidelberg, Heidelberg, W. Germany). *Cell Tissue Res.* 175(2):227-243; 1976.

The rate of synthesis and discharge of regular and fucosylated secretory proteins in isolated rat pancreatic lobules was studied under control conditions and after *in vivo* prestimulation with cerulein (2.5 x 10^{-7} g/kg/hr). Both labeled leucine and fucose were incorporated into pancreatic proteins at a linear rate, which was potentiated by *in vivo* stimulation. In pulse-chase experiments, both regular and fucosylated secretory proteins were discharged into the medium in parallel. The *in vivo* pretreatment with cerulein caused an earlier discharge and increased the total amount of protein released. Kinetic analysis of unstimulated (baseline) discharge of both classes of secretory proteins indicated a striking *in vitro* sensitivity by the previous *in vivo* treatment with cerulein. The biochemical data were compared to the fine structure of the Golgi complex under both control and prestimulated conditions. The Golgi stacks were composed of four to six individual cisternae, which in some cases were connected by intercisternal pores. Transporting vesicles were observed fusing along the total length of the outermost cisterna on both the *cis*- and *trans*-side and with the lateral ends of the intermediate cisternae. Under control conditions, only the last *trans*-cisterna contained some electron-opaque material: *in vivo* prestimulation led to distension and filling of all cisternae in an individual Golgi unit. Numerous stages of transformation of the last *trans*-cisterna into condensing vacuoles were observed, lending support to the hypothesis that during packaging of secretory products, the membranes of the Golgi complex undergo a continuous turnover.

2836 EFFECTS OF DUODENAL ALKALINIZATION ON PANCREATIC SECRETION.

(Eng.) Takeshima, T.; Adler, M.; Nacchiero, M.; Rudick, J.; Dreiling, D. A. (Medical Center, Tsukuba Univ., Japan). *Am. J. Gastroenterol.* 67(1):54-62; 1977.

To further study the feed-back effects of intraduodenal pancreatic juice or alkaline solutions on gastric and pancreatic secretion, the effects of duodenal alkalinization were evaluated in seven dogs, including two antrectomized dogs with chronic duodenal fistulas. The continuous i.v. injection of secretin plus cholecystokinin-pancreozymin (CCK-PZ) was administered as a stimulus for pancreatic secretion. The intraduodenal infusion of alkaline solutions, such as pancreatic juice (pH 8.6), bile (pH 8.1), bicarbonate solution (160 mEq/l, pH 8.6), and TRIS buffer solution (0.3 M, pH 9.5), caused a moderate increase in protein output and a modest or no increase in flow, but no change in bicarbonate output. During the infusion of pancreatic juice, varied doses of secretin (0, 0.015, 0.03, 0.06 U/kg/min), or secretin (0.03 U/kg/min) plus CCK-PZ (0.05 U/kg/min) were administered i.v. During secretin (0.03 U/kg/min) stimulation, flow increased 17.7%, which was statistically significant. Protein output also showed a significant increase of 35.7%. There was, however, no response of the pancreas to the infusion of pancreatic juice when the gland was stimulated by secretin plus CCK-PZ. Antrectomy did not alter the effect of alkaline intraduodenal infusions on pancreatic secretion. Alkalinization of the duodenum significantly increases secretin-stimulated pancreatic enzyme secretion. It is suggested that this phenomenon derives from a "CCK-PZ" effect, most likely resulting from release of duodenal gastrin by the increases in duodenal pH.

2837 NON-PARALLEL RESPONSE OF AMYLASE AND CHYMOTRYPSINOGEN BIOSYNTHESIS FOLLOWING PANCREATIC STIMULATION: A POSSIBLE EXPLANATION FOR OBSERVED NON-PARALLELISM IN PANCREATIC SECRETION.

(Eng.) Dagorn, J. C.; Paradis, D.; Morisset, J. (Unite de Recherches de Pathologie Digestive, U-31 INSERM, 46 chemin de la Gaye, Marseille F-13009, France). *Digestion* 15(2):110-120; 1977.

Pancreatic synthesis and secretion of amylase (Am) and chymotrypsinogen (ChTg) were studied in rats stimulated by gastric intubation of oleic acid. The ratio of Am to ChTg synthesis, as measured by ^{14}C-phenylalanine incorporation, showed a 65% decrease within 15 min of stimulation, followed by a gradual return to control values after 90 min. Measurements of the intrapancreatic levels of Am and ChTg showed a 33% decrease in the Am:ChTg ratio within 30 min, followed by a return to normal. The Am:ChTg ratio in the pancreatic juice decreased dramatically after oleic acid stimulation, since the ChTg output increased 15 times, while the Am output only tripled. Since the nonparallelism in rates of biosynthesis only partially accounts for the nonparallelism in rates of secretion, it is suggested that different mechanisms control these two processes.

2838 ADENYL CYCLASE AND CYCLIC AMP (cAMP) IN ACUTE EXPERIMENTAL PANCREATITIS. BIOCHEMICAL AND HISTOCHEMICAL STUDIES.

(Eng.) Gabrys-Pomykala, B. F.; Holian, O.; MacKenzie, M.; Nyhus, L. M.; Bombeck, C. T. (Abraham Lincoln Sch. Medicine, Univ. Illinois Medical Center, Chicago, IL 60612). *Am. J. Surg.* 133(2):156-162; 1977.

The relationship of adenylate cyclase and adenosine 3',5'-monophosphate levels to early events in hemorrhagic pancreatitis was studied in dogs using an experimentally induced model of the disease. Anesthetized and laparotomized dogs were given a single injection of 10 cm^3 trypsin (30,000 I.U.), 3 cm^3 bile, and 4 cm^3 blood into the caudal major pancreatic duct. Induction of pancreatitis occurs within 15 min, as indicated by visible hemorrhage and increased levels of serum amylase and lipase. Concommitantly, basal adenylate cyclase activity dropped from 3.39 ± 0.21 to 1.66 ± 0.54 pmol/mg protein/min. By 30 min, basal activity was negligible. Adenylate cyclase activity was stimulated by sodium fluoride and remained constant for 30 min, subsequently falling to background levels by 60 min. However, levels of cAMP in the tissue did not decline below a normal basal control of 0.88 ± pmol/mg wet tissue by 60 min. Histochemical studies localized adenylate cyclase of normal pancreatic tissue to the luminal membranes of capillaries and to the plasma membranes of endocrine cells, but not to the exocrine cell membranes. Progressive disappearance of adenylate cyclase activity appears to result from autodigestion of membranes by proteases released during acute cell breakdown.

2839 EFFECTS OF PARTIAL SURGICAL PANCREATECTOMY IN RATS. I. PANCREATIC REGENERATION.

(Eng.) Pearson, K. W.; Scott, D.; Torrance, B. (Manchester Royal Infirmary, Manchester, M13 9WL, England). *Gastroenterology* 72(3):469-473; 1977.

Because of limited and often conflicting reports on the effects of partial pancreatectomy in mammals, the capacity for pancreatic regeneration in male Wistar rats was determined after 50, 70, or 90% pancreatectomy. In weight-matched controls, pancreatic growth was still taking place, but ceased after 2 months. Growth of the residual pancreas in operated animals over this 2-month period was greate than that in controls, and the final weight of the residual pancreas was 21, 32, and 78% greater than that of the corresponding segments in sham-operated animals after 50, 70, and 90% resection, resp. Proliferation of acinar cells was assayed by autoradiographic detection of tritiated thymidine incorporation in controls and after 90% resection. Proliferation of acinar cells in control animals during the first 2 weeks of the experiment was significantly higher than it was later in the experiment, when it fell to very low levels. Proliferation in 90% resected animals was markedly higher than that in controls 2-5 days after resection and, together with th limited hypertrophy occurring at this time, adequately accounted for the increase in weight of the

esidual pancreas during the first 2 weeks. The in-
rease in pancreatic weight in control or resected
nimals between 2 weeks and 2 months cannot be ex-
lained, either in terms of hypertrophy or hyper-
lasia of acinar cells.

SECRETION AND METABOLISM

Hepatobiliary Tract

2864 THE MIXED LEUCOCYTE-MACROPHAGE MIGRATION TEST IN ACTIVELY SENSITISED AND TRANSFER FACTOR-TREATED RHESUS MONKEYS: PRELIMINARY OBSERVATIONS ON HBsAg SPECIFIC TRANSFER FACTOR. (Eng.) Scalise, G.; Mazaheri, M. R.; Hamblin, A. S.; Gioannini, P.; Zuckerman, A. J.; Dumonde, D. C. (London Sch. Hygiene and Tropical Medicine, London, England). *Minerva Gastroenterol.* 22(3):257-260; 1976.

Studies were carried out in Rhesus monkeys to determine whether dialysable transfer factor (TF) confers cellular immune responsiveness to keyhole limpet hemocyanin (KLH), tuberculin PPD, and hepatitis B surface antigen (HBsAg) on operationally naive animals. Immunized donors and TF recipients were tested by a 48-hr skin test of delayed hypersensitivity (KLH=10 μg, PPD=10 μg, HBsAg=50 μg) and by a mixed cell migration technique. Following active sensitization with the antigens in complete Freund's adjuvant, both migration reactivity and delayed hypersensitivity was conferred to the monkeys towards the end of the third week. In contrast, when recipient monkeys were treated with TF derived from immunized animals, the TF-treated monkeys acquired migration responses, but not delayed hypersensitivity. The mixed leukocyte-macrophage migration test is suitable for studying the response of recipient animals. If it can be confirmed that TF for HBsAg works in the rhesus monkey, a useful model for hepatitis B immunotherapy will be available.

2865 THE HEPATIC HANDLING OF ^{131}I-LABELED SULFOBROMOPHTHALEIN IN THE DOG. COMPARISON WITH SULFOBROMOPHTHALEIN. (Eng.) Glasinovic, J. C.; Delage, Y.; Erlinger, S. (INSERM, Hopital Beaujon 100, Boulevard du General Leclerc, 92110 Clichy, France). *Biomedicin (Express)* 25(7):255-258; 1976.

The hepatic uptake and biliary excretion of BSP and ^{131}I-labeled BSP were compared in the dog.

one series of experiments, a compartmental alysis of BSP and ^{131}I-labeled BSP disappear- ce curves was performed after the simultaneous jection of 5 mg/kg of BSP and 10 µCi of ^{131}I- beled BSP. Both the plasma to liver and liver bile transfer rates were significantly lower r ^{131}I-labeled BSP (0.150 ± 0.030 mg/mg/min d 0.006 ± 0.002 mg/mg/min, resp.) than for P (0.282 ± 0.062 and 0.044 ± 0.016 mg/mg/min, sp., $p<0.001$). The liver to plasma rates re not significantly different. In the second ries of experiments, the hepatic uptake of BSP d ^{131}I-labeled BSP was estimated by the multiple dicator dilution technique. The extraction of SP (59% ± 5) was significantly higher than that ^{131}I-labeled BSP (35% ± 5, $p<0.001$). It is con- uded that the labeling of BSP with ^{131}I signi- cantly modifies the hepatic handling of the e; ^{131}I-BSP cannot therefore be used as a acer of BSP.

366 EFFECT OF GLYCODIHYDROFUSIDATE ON SULFO-BROMOPHTHALEIN TRANSPORT MAXIMUM IN THE MSTER. (Eng.) Delage, Y.; Dumont, M.; Erlinger, (Hopital Beaujon, 92110 Clichy, France). *Am. J. ysiol.* 231(6):1875-1878; 1976.

e effect of sodium glyco-24,25-dihydrofusidate on P transport maximum (Tm) and biliary lipid secre- on was compared to the effect of sodium tauro- olate in hamsters. Biliary phospholipid increased om a control level of 8.8 ± 2.52 to 19.18 ± 7.86 ol/min/100 g ($p<0.02$) during glycohydrofusidate fusion (1.4 µmol/min/100 g x 90 min, i.v.) and from 29 ± 1.66 to 16.72 ± 3.87 nmol/min/100 g ($p<0.01$) ring taurocholate infusion. Cholesterol secre- on was also significantly elevated by both infu- ons. These results suggest that both compounds creased the biliary secretion of micelle-forming mpounds. In contrast, only taurocholate increased P Tm into bile (from a control level of 35.60 ± 98 to 46.55 ± 7.53 nmol/min/100 g, $p<0.01$), while ycodihydro-fusidate administration decreased Tm from 39.23 ± 8.49 to 8.33 ± 2.84 nmol/min/100 g, <0.01). This suggests that the increase in BSP observed during taurocholate administration is t the result of micellar sequestration. It uld, instead, be the consequence of a specific ffect of bile salts on the dye transport system.

867 LIPOPROTEIN REGULATION OF 3-HYDROXY-3-METHYLGLUTARYL COENZYME A REDUCTASE ACTIV- TY IN RAT LIVER CELL CULTURES. (Eng.) Breslow, J. .; Lothrop, D. A.; Clowes, A. W.; Lux, S. E. Children's Hosp. Medical Center, 300 Longwood Ave., oston, MA 02115). *J. Biol. Chem.* 252(8):2726-2733; 977.

primary cell culture technique was used to study the ffects of lipoproteins on the 3-hydroxy-3-methyl- lutaryl coenzyme A (HMG-CoA) reductase activity in prague-Dawley rat hepatocytes. Lipoproteins pre- ared from normocholesterolemic rat and human plasma, ncluding low density lipoproteins, did not inhibit epatocyte HMG-CoA reductase activity, whereas very low density lipoproteins and high density lipoproteins isolated from the same sources were stimulatory. A lipoprotein was isolated from the plasma of cholesterol-fed rats that did inhibit hepatocyte HMG-CoA reductase activity. It was mainly $d<1.019$ g/ml and had β mobility on lipoprotein electrophoresis. The lipoprotein was compared to the comparable density fraction in the normocholesterolemic rat plasma; there was no appreciable size difference by negatively stained electron micrographs. However, two important differences in chemical composition were evident: in the inhibitory lipoproteins, the percent of total apoprotein, which was in the region of M_r=35,000, was increased 1.5- to 2-fold, and there was a marked increase in cholesterol ester content. These chemical characteristics may be required for lipoproteins to regulate hepatocyte cholesterol synthesis. Primary cell culture of rat hepatocytes appears to be a useful system in which to study hepatic cholesterol metabolism.

2868 EFFECT OF ALCOHOL ON THE HEME AND PORPHYRIN SYNTHESIS: INTERACTION WITH PHENOBARBITAL AND PYRAZOLE. (Eng.) Held, H. (Medizinische Universitatsklinik Tubingen, Abteilung I, D-74 Tubingen, W. Germany). *Digestion* 15(2):136-146; 1977.

The mechanism of hepatic δ-aminolevulinic acid synthetase (ALA synthetase) induction by alcohol and the effect of alcohol on liver porphyrin synthesis and accumulation were investigated in male Sprague-Dawley rats. After a single dose of alcohol (2 g/kg, p.o.), the activity of hepatic ALA synthetase in starving rats increased two- to threefold within 3 hr. The porphyrin concentration in the livers was increased maximally by 75%. The activities of δ-aminolevulinic acid dehydratase (ALA dehydratase), microsomal monoxygenase, and cytochrome P-450 and ATP concentrations in the liver were not altered. A previous injection of pyrazole (6 µmol/kg) abolished the inducing effect of alcohol on ALA synthetase. The inducing effect of alcohol was increased by a previous injection of phenobarbital (80 mg/kg). The activity of the microsomal monoxygenase and the concentration of cytochrome P-450 were not altered by replacing the drinking water with an 8% alcohol solution. The activity of the ALA synthetase in the liver of these animals was increased three- to fourfold only when they were starved before sacrifice; in fed animals, the activity of this enzyme was in the range of the control animals. The increase of the cytochrome P-450 concentration in the liver after 80 mg phenobarbital sodium/kg was partially inhibited by alcohol. Alcohol appears to differ from other known porphyrinogenic agents. An alteration of the cytochrome P-450 concentration could not be demonstrated as the cause of the induction of the ALA synthetase. The observed porphyrinogenic effect is not caused by alcohol itself, but either by its metabolites or by the changes of the liver metabolism caused by the effect of alcohol on the NAD/NADH ratio.

2869 ELIMINATION OF VASOPRESSIN BY THE NORMAL AND THE DAMAGED LIVER: EXPERIMENTS ON UN-ANAESTHETIZED NORMAL AND THIOACETAMIDE TREATED RATS, WITH A NOTE ON THE INFLUENCE OF ETHANOL. (Eng.) Aziz, O.; Schmidt, W. (Institut fur Angewandte Physiologie der Philipps-Universitat Marburg, Lahnberge, D-3550 Marburg, W. Germany). *Pfluegers Arch.* 367(2):165-168; 1976.

The possibility that the damaged liver eliminates antidiuretic hormone (ADH) was investigated in female Wistar rats with thioacetamide-damaged livers. Arginine vasopressin was infused (16 µU/min) into the vena portae or the vena cava of unanesthetized rats in water diuresis produced by an intraduodenal infusion of tap water. The differential antidiuretic response of the same animal to the vasopressin infusions was used to calculate the extraction fraction of ADH by the liver. In normal rats, no extraction was detected. In rats in which 5% ethanol had been infused in place of tap water, the liver extracted 10% of the ADH infused into the portal vein. The thioacetamide-damaged livers extracted 60%. Disturbances of liver cell function by narcotics and substances causing liver damage may liberate ADH-destroying enzymes into the liver sinusoids.

2870 ETHANOL METABOLISM IN PERFUSED RAT LIVER AT LOW ETHANOL CONCENTRATIONS: INVOLVEMENT OF ALCOHOL DEHYDROGENASE IN THE ADAPTIVE INCREASE IN ETHANOL METABOLISM DUE TO CHRONIC PRETREATMENT WITH ETHANOL. (Eng.) Thurman, R. G.; Scholz, R. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA 19174). *Hoppe-Seyler's Z. Physiol. Chem.* 357(10):1443-1446; 1976.

Ethanol metabolism was studied in the perfused livers of rats pretreated for 5 weeks with 20% ethanol in the drinking water. The rate of ethanol uptake by livers perfused with 1 mM ethanol was about 50% greater in the treated donor animals than in the untreated controls, indicating that an adaptive increase in ethanol metabolism exists at low ethanol concentrations. Perfusion with 4-methylpyrazole (0.7 mM) caused a rapid inhibition of ethanol uptake in livers from both ethanol-treated and control rats. Residual ethanol uptake was less than 5% of basal values and was indistinguishable from vaporization of ethanol from the liver surface. Since an adaptive increase was observed at 1 mM ethanol, which was almost totally 4-methylpyrazole sensitive, it is concluded that alcohol dehydrogenase, and not catalase or other enzyme systems, is responsible for the adaptive increase in ethanol metabolism.

2871 EFFECT OF ETHANOL ON COLLAGEN FORMATION IN DIETARY CIRRHOSIS IN THE RAT. (Eng.) Henley, K. S.; Laughrey, E. G.; Appelman, H. D.; Flecker, K. (Medical Res. Building, Univ. Hosp., Ann Arbor, MI 48104). *Gastroenterology* 72(3):502-506; 1977.

Studies were carried out in male Sprague-Dawley rats to determine whether ethanol increases the rate of collagen deposition in the pathogenesis of dietary cirrhosis and, if so, whether this occurs as a result of increased rates of synthesis or decreased rates of collagen breakdown. Ethanol (10 or 15% in the drinking water) increased the amount of collagen in the livers of rats receiving a cirrhogenic diet (high in fat, and low in protein, choline, and vitamin B_{12}). This effect of ethanol was most striking in the animals receiving 10% ethanol. Ethanol lowered the amount of labeled proline incorporated into hydroxyproline and, therefore, into collagen. The amount of labeled hydroxyproline remaining in the liver 7 days after injection was greater in the rats receiving 10% ethanol than in the pair-fed controls. A net increase in collagen deposition attributable to ethanol was associated with a lowered rate of collagen synthesis. The main action of ethanol in increasing the rate of collagen deposition, therefore, must be inhibition of collagen breakdown.

2872 CHANGES IN HEPATIC COLLAGEN METABOLISM IN RATS PRODUCED BY CHRONIC ETHANOL FEEDING. (Eng.) Mezey, E.; Potter, J. J.; Slusser, R. J.; Abdi, W. (Baltimore City Hosp., 4940 Eastern Ave., Baltimore, MD 21224). *Lab. Invest.* 36(2):206-214; 1977.

The effect of 6 months of ethanol feeding on parameters of hepatic collagen metabolism was studied in male Wistar rats. Ethanol feeding (36.1% of diet) resulted in small increases in the fibrous and groun substance components of hepatic collagen, as measure by increases in collagen-bound hydroxyproline and hexosamine, resp. Histologically, fatty infiltratio without necrosis or fibrosis was found in the liver. The activity of collagen proline hydroxylase and the incorporation of labeled proline into collagen by liver slices were not changed by ethanol feeding. Ethanol feeding resulted in increases in the concentration of protein and DNA in the Kupffer cells, but in no changes in collagenase activity. An increase in collagen degradation was suggested, however, by t increase in the urinary excretion of hydroxyproline (108.8-188.1 µg/24 hr in controls; 177.7-275.8 µg/24 hr in ethanol-treated animals) and glycosaminoglycan (199.1-263.6 µg/24 hr in controls; 215.9-324.6 µg/24 hr in treated animals) found after 2 and 6 months of ethanol feeding, resp. This study demonstrates that fatty infiltration of rat liver after prolonged ethanol feeding is associated with increased deposition of chemically detectable collagen and evidence increased collagen degradation, although no signific changes in parameters associated with hepatic collag synthesis were found.

2873 ACCENTUATION OF ETHANOL-INDUCED FATTY LIV BY PHENOBARBITONE. (Eng.) Marsh, A. R.; Fraser, H. S.; Breckenridge, A.; Lewis, B.; Thompso G. R. (Royal Naval Hosp., Haslar, Hants., England). *Clin. Sci. Mol. Med.* 52(2):219-222; 1977.

The previous report of a protective action of pheno barbitone against ethanol-induced fatty liver was r examined. Male Wistar rats received liquid formula diets alone or supplemented with either ethanol (36 of calories) or phenobarbitone (0.5 mg/ml) or both. Plasma triglyceride concentrations were significant increased in rats given phenobarbitone alone (3,240 290 µM, $p<0.01$) or phenobarbitone plus ethanol (2,8

70 μM, $p<0.02$), but not in those given ethanol alone, ı whom there was a significant fall (730 ± 50 μM, <0.005), as compared to control rats (1,240 ± 120 μM). .asma cholesterol concentrations rose significantly ı all three test groups ($p<0.001$). Liver triglycer-le concentrations rose in rats given ethanol alone 24.2 ± 1.5 mg/g) in comparison with controls (17.8 0.6 mg/g, $p<0.005$), but not in those given phenobar-.tone alone. A striking increase in liver trigly-eride levels occurred in rats given both ethanol and ıenobarbitone (113 ± 11.2 mg/g, $p<0.001$). Parallel ıanges occurred in liver cholesterol. These findings ıpport the concept that ethanol exerts an inhibitory ffect on the secretion of very-low-density lipopro-ein. Thus, the striking increase in liver trigly-eride levels in rats given both ethanol and phenobar-.tone was presumably due to a combination of in-reased synthesis and reduced secretion of triglycer-les.

374 KINETIC STUDIES ON THE ENZYMES CONJUGATING BILE ACIDS WITH TAURINE AND GLYCINE IN VINE LIVER. (Eng.) Vessey, D. A.; Crissey, M. ; Zakim, D. (Veterans Admin. Hosp., San Francisco, 94121). *Biochem. J.* 163(1):181-183; 1977.

kperiments were carried out in bovine liver to de-ermine whether there are separate enzymes for .ycine and taurine conjugation of bile acids. ıis question was investigated by the technique of .ternative-substrate inhibition. The initial rate reaction of choloyl-coenzyme A (choloyl-CoA) .th ^{14}C-taurine was determined with ^{14}C-taurine resent at its K_m concentration (0.75 mM). Un-ıbeled glycine was added at a concentration of 2 mM, which is three times its K_m concentration ı the glycine-conjugation reaction. This concen-ration caused no inhibition of the conjugation of C-taurine. The initial rate of ^{14}C-glycine con-ıgation was unaffected by the addition to the ssay of a concentration of unlabeled taurine three imes its K_m in the taurine reaction. These data emonstrate that there are separate active sites or glycine and taurine in the conjugation reactions ıd that there are separate enzymes for the con-ıgation of cholic acid with glycine and taurine.

375 EFFECT OF DEOXYCHOLIC ACID INGESTION ON BILE ACID METABOLISM AND BILIARY LIPID SE-RETION IN NORMAL SUBJECTS. (Eng.) LaRusso, N. F.; zczepanik, P. A.; Hofmann, A. F. (Dept. Biochemicall ytology, Rockefeller Univ., New York, NY 10021). *astroenterology* 72(1):132-140; 1977.

he effect of deoxycholic acid ingestion on bile cid kinetics, biliary bile acid composition, and iliary lipid secretion was studied in seven healthy olunteers. Bile acid kinetics were measured by iso-ope dilution, and hourly outputs of bile acid, cho-esterol, and phospholipid were quantitated by a duo-enal perfusion technique during a 24-hr period that ncluded three liquid meals and an overnight fast. iliary bile acid composition was assessed by coupled as chromatography-mass spectrometry. After deoxycho-ic acid (750 mg/day, 4-8 weeks) ingestion, biliary ile acids became composed of predominantly deoxycholyl conjugates, and deoxycholic acid pools increased fourfold. Both chenodeoxycholic and cholic acid pools decreased, and daily synthesis of each of the primary bile acids was inhibited by 50%. Total bile acid pools did not change in any consistent manner. Daily bile acid secretion increased slightly during deoxycholic acid ingestion, and recycling frequency varied reciprocally with the total bile acid pool both before and during deoxycholic acid treatment. Deoxycholic acid ingestion caused no change in either the daily secretion of cholesterol or lecithin, or the cholesterol saturation of fasting-state bile, which remained unsaturated throughout the study. SGOT levels increased to 4 times the upper limits of normal in two subjects, but these levels promptly returned to normal when deoxycholate feeding was stopped. Serum cholesterol levels decreased an average of 15% in every subject during deoxycholic acid administration. The results give no evidence for a direct role of deoxycholate in the pathogenesis of cholesterol cholelithiasis.

2876 EFFECT OF DIETARY LACTOSE AT LEVELS COMPARABLE TO HUMAN CONSUMPTION ON CHOLESTEROL AND BILE ACID METABOLISM OF CONVENTIONAL AND GERMFREE RATS. (Eng.) Wostmann, B.; Bruckner-Kardoss, E.; Beaver, M.; Chang, L.; Madsen, D. (Dept. Microbiology, Univ. Notre Dame, Notre Dame, IN 46556). *J. Nutr.* 106(12):1782-1790; 1976.

The effect of lactose on the microbial modification of acid and neutral sterols was studied in rats during a 3-month feeding trial. Lactose intake, ranging up to 30% of total diet, increased β-muricholic (β-MC), but not cholic acid concentrations in conventional (CV) rat small intestine; at the 20% and 30% intake levels, the intestinal cholic:β-MC ratio approached that in germ-free (GF) rats. Total intestinal bile acid (BA) content increased by approximately one-third, but remained at less than half the value found in GF rats. At lactose intake levels within a range corresponding to the recommended consumption of dairy products for adult man (5-10%), only moderate changes in intestinal, and little change in fecal BA were found during and after the 3-month period. Intestinal β-MC was increased in the presence and in the absence of an intestinal microflora. Experiments with GF rats fed 10% lactose or 10% maltose indicated that this increase is evoked similarly by both carbohydrates. The slight increase in serum cholesterol levels seen with disaccharide feeding, which became evident only in the GF rats, was again not specific for lactose. Lactose feeding had no effect on liver cholesterol levels. Comparison of CV rats fed nonsterile and radiation-sterilized lactose-containing diets suggested that this mode of sterilization has only a minor influence on the resulting data. Sterilization of diet by irradiation with 3.5 to 4.0 x 10^6 rads was preferable to autoclaving. The data indicate that there is no major effect specifically related to a normal dietary intake of lactose on cholesterol and BA metabolism of the adult rat.

2877 SUBCELLULAR PATHOLOGY OF RAT LIVER IN CHOLESTASIS AND CHOLERESIS INDUCED BY BILE SALTS. 1. EFFECTS OF LITHOCHOLIC, 3β-HYDROXY-5-CHOLENOIC, CHOLIC, AND DEHYDROCHOLIC ACIDS. (Eng.)

Miyai, K.; Richardson, A. L.; Mayr, W.; Javitt, N. B. (San Diego Sch. Medicine, La Jolla, CA 92093). *Lab. Invest.* 36(3):249-258; 1977.

The effects of single or combined administration of sodium taurolithocholate, taurocholate, and 3β-hydroxy-5-cholenoic, and dehydrocholic acids (TLC, TC, BHC, and DHC, resp.) on bile flow and hepatic ultrastructure were studied in female Wistar rats with or without cannulation of the common bile duct. Cholestasis or choleresis was induced by the i.v. infusion of one of the bile acids (0.05 to 0.2 μmol/min/100 g). Bile flow was monitored and ultrastructural changes were examined up to 3 hr after bile salt administration. TC induced acute cholestasis and ultrastructural alterations consisting primarily of dilation of bile canaliculi, loss of canalicular microvilli, and lamellar transformation of the canalicular membrane. Occasionally, crystalline precipitates were present within the canalicular lumen and in the pericanalicular region of hepatocytes. BHC caused similar, but less severe, ultrastructural changes to those induced by TLC. DHC had a greater choleretic effect than TC, but neither induced noteworthy ultrastructural change. When infused simultaneously with TLC, TC reversed cholestasis and largely prevented development of the ultrastructural changes induced by TLC. In contrast, simultaneous infusion of DHC prevented neither cholestasis nor development of the ultrastructural changes induced by TLC, which were more striking than those caused by TLC or BHC alone. In addition, structural changes associated with cholestasis induced by these bile salts, either singly or in combination, were more pronounced and frequent in the periportal zone than elsewhere in the hepatic lobule. The results suggest that both TLC and BHC induce cholestasis by affecting the structural and functional integrity of the bile canalicular membrane and also, in part, by forming untransportable precipitates. The contrasting effects of TC and DHC on TLC-induced changes suggest that TC overcomes the effect of TLC by solubilizing it into mixed micelles, but DHC and its metabolites have little or no such effect. The intralobular variation in severity of ultrastructural changes probably reflects the accumulation of bile salts in greater concentrations in hepatocytes near the portal triads.

2878 EFFECT OF MICROSOMAL ENZYME INDUCERS ON THE BILIARY EXCRETION OF AN EXOGENOUS LOAD OF BILIRUBIN IN NEWBORN RATS. (Eng.) Klaassen, C. D. (Univ. Kansas Medical Center, Kansas City, KS 66103). *Proc. Soc. Exp. Biol. Med.* 153(2):370-373; 1976.

Experiments were carried out in newborn Sprague-Dawley rats to determine whether the biliary excretion of an exogenous load of bilirubin is impaired and whether there is a difference in the ability of various microsomal enzyme inducers to enhance the development of the processes responsible for its excretion. Rats 15 days of age and younger were less efficient in excreting ^{3}H-labeled bilirubin into the bile than older rats. Rats 1, 6, 11, 16, 21, or 26 days old were pretreated for 4 days with phenobarbital (33 or 50 mg/kg), spironolactone (75 mg/kg), pregnenolone-16α-carbonitrile (PCN, 75 mg/kg), or 3-methylcholanthrene (3-MC, 20 mg/kg). On the fifth day, ^{3}H-bilirubin was administered (30 mg/kg, i.v.). Twenty minutes later, the amount of bilirubin excreted into the intestine was determined. Spironolactone and PCN enhanced the biliary excretion of bilirubin, but phenobarbital and 3-MC were without effect. The results show that the biliary excretion of exogenous unconjugated bilirubin is immature in the newborn rat.

2879 PLASMA PROTEIN SYNTHESIS BY ISOLATED RAT HEPATOCYTES. (Eng.) Crane, L. J.; Miller D. L. (Roche Inst. Molecular Biology, Nutley, NJ 07110). *J. Cell Biol.* 72(1):11-25; 1977.

A new method of preparing rat hepatocytes with extended viability was developed to study the role of hormones and other plasma components upon secretory protein synthesis. Hepatocytes maintained in minimal essential medium reduced the levels of all amino acids in the medium except the slowly catabolized amino acids leucine, isoleucine, and valine, which steadily increased as the result of liver protein catabolism. Although the liver cells catabolized 10-15% of their own protein during a 20-hr incubation, the cells continued to secrete protein in a linear fashion throughout the period. Cells from nonadrenalectomized animals showed preinduction of tyrosine amino transferase, having a high level of enzyme at the time of isolation, which showed only an increase of approximately 60% upon incubation with cortisol. In contrast, cells from adrenalectomized animals initially had a low level of enzyme, which increased fourfold over a period of 9 hr. The effects of both epinephrine and cortisol on protein synthesis were also much larger in cells from adrenalectomized animals. After a delay of several hours, cortisol increased fibrinogen synthesis sharply, so that at the end of the 20-hr incubation, cells treated with hormone secreted nearly 2.5 times as much fibrinogen as control cells The effect was found to be specific; cortisol stimulated neither albumin secretion nor intracellular protein synthesis. The combination of cortisol and epinephrine strongly depressed albumin synthesis in both types of cells. Insulin enhanced albumin and general protein synthesis, but had little effect on fibrinogen synthesis.

2880 THE ENDOPLASMIC RETICULUM OF THE RAT LIVER CELL IN EXPERIMENTAL MECHANICAL CHOLESTASIS. CORRELATED BIOCHEMICAL AND ULTRASTRUCTURAL-MORPHOMETRIC STUDIES ON STRUCTURE AND ENZYME COMPOSITION. (Eng.) Denk, H.; Eckerstorfer, R.; Rohr, H. P. (Univ. Vienna Sch. Medicine, Vienna, Austria). *Exp. Mol. Pathol.* 26(2):193-203; 1977.

The structure and enzyme composition of the endoplasmic reticulum (ER) and smooth (SER) and rough (RER) microsomal subfractions derived from choledochus-ligated rat livers were studied using biochemical and ultrastructural morphometric methods. Mechanical cholestasis resulted in an increase in the surface density of ER per total liver (4.06 ±

0.35 m^2/cm^3 of liver versus 1.95 ± 0.14 m^2/cm^3 in controls), but neither the protein/phospholipid nor the SER/RER ratios of the microsomal membranes were affected. ER in cholestasis was poor in cytochrome P-450, the P-450 loss being more pronounced in the RER than in the SER. The decrease in cytochrome b_5 was less pronounced. Microsomal UDP-glucuronyl transferase activity remained unchanged; total activity in the liver was elevated in proportion to the increase in total microsomal protein. Glucose-6-phosphatase activity was significantly decreased in SER (6.50 versus 10.59 μmol P/mg microsomal protein/20 min) and RER (6.10 versus 10.27 μmol P/mg/20 min). Benzpyrene hydroxylase activity of liver microsomes *in vitro* was greatly impaired in cholestasis (20% of the controls). In contrast to aminopyrine-*N*-demethylase, the benzpyrene hydroxylase activity did not correlate with P-450 loss or loss of P-450 reductase. This may be due to a predominant alteration of the P-450 species specifically engaged in benzpyrene metabolism. Cholestasis had no effect on microsomal lipid peroxidation and fatty acid desaturation *in vitro*. Selective ligation of the middle lobe of the liver was not accompanied by an increase in the weight of the obstructed lobe or by inhibition of microsomal aminopyrine-*N*-demethylation. However, an increase in microsomal protein, as well as a decrease in the specific microsomal content in P-450 and b_5 and in glucose-6-phosphatase activity, was observed, similar to the situation seen in complete cholestasis.

2881 EFFECT OF 3-AMINO-1,2,4-TRIAZOLE TREATMENT ON CATALASE ACTIVITY AND TRIGLYCERIDE LEVEL IN FATTY LIVER OF THE RAT.

(Eng.) Ishii, H.; Suga, T.; Niinobe, S. (Tokyo Coll. Pharmacy, 1432-1 Horinouchi, Hachioji, Tokyo 192-03, Japan). *Biochem. Pharmacol.* 26(7):625-628; 1977.

The effect of 3-amino-1,2,4-triazole (AT) pretreatment on the triglyceride (TG) level in CCl_4 (2.5 ml/kg, s.c.)-, ethanol (6 g/kg, p.o.)-, or ethionine (1 g/kg, i.p.)-induced fatty liver in Wistar rats was studied, and the relationship between liver catalase activity and TG metabolism was investigated. The intoxication by each hepatotoxin increased the liver TG level in the rats. However, when the rats were pretreated with AT (1 g/kg, i.p.), the liver TG level decreased about 50%, and the liver catalase activity was inhibited about 85%. When AT and CCl_4, were injected simultaneously, they repressed about 50% of the increase of the TG level caused by the intoxication of CCl_4. When AT alone was injected before the intoxication of ethanol, the liver catalase activity decreased by 50% of that of the ethanol group, and the increase in liver TG level was lowered by 40%. When AT was injected after ethanol, the increase in liver TG level was depressed, although there was no decrease in catalase activity. Although the serum TG level was decreased by CCl_4 treatment and increased by the ethanol treatment, AT showed no effect on these changes. These results suggest that AT acts independently on the TG level and catalase activity in the liver.

2882 CHIMPANZEE LIVERS AFTER INFECTION WITH HUMAN HEPATITIS VIRUSES A AND B: ULTRASTRUCTURAL STUDIES.

(Eng.) Schaffner, F.; Dienstag, J. L.; Purcell, R. H.; Popper, H. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Arch. Pathol. Lab. Med.* 101(3):113-117; 1977.

To determine whether hepatitis A virus and hepatitis B virus produce different hepatic lesions, liver biopsy specimens from chimpanzees experimentally infected with one of the two viruses were examined ultrastructurally. Hepatitis B was recognized by the presence of hepatitis B core particles in hepatocellular nuclei. Hepatitis A was characterized by unidentified large, dense, and more irregular heterochromatin-like particles in hepatocellular nuclei, coincidental with peak aminotransferase activities. As type A hepatitis illness became manifest in the animals, mitochondrial cristae were curled and attenuated, and clusters of endoplasmic reticulum were tightly packed. The livers in viral hepatitis B showed mainly hypertrophy of tubular smooth endoplasmic reticulum. This suggests different pathogenetic mechanisms in A and B chimpanzee viral hepatitis.

2883 EFFECT OF INSULIN AND GLUCAGON ON FULMINANT MURINE HEPATITIS.

(Eng.) Farivar, M.; Wands, J. R.; Isselbacher, K. J.; Bucher, N. L. R. (Harvard Medical Sch., Boston, MA). *N. Engl. J. Med.* 295(27):1517-1519; 1976.

The ability of insulin and glucagon to enhance liver regeneration was studied in CD mice with experimental viral hepatitis. All mice received 16 complement fixation units of a suspension of A-59 murine hepatitis virus, i.p., immediately followed by an infusion containing a mixture of electrolytes, 10% glucose, and amino acids; the experimental animals also received insulin (20 U) and glucagon (0.3 mg), either alone or in combination. The infusion of virus and nutrient mixture alone resulted in death of over 80% of the animals within 2 days, and in the remainder within 4 days. The immediate administration of glucagon and insulin combined more than doubled mean survival time ($p<0.01$) and led to complete recovery in 40% of the mice; the infusion of insulin alone had a modest effect on survival ($p<0.025$), while glucagon alone had no effect. When treatment was delayed for 24 hr, the mean survival in mice treated with both hormones was still increased ($p<0.05$), and 15% recovered. At 24 hr after infection in controls, liver damage was 4+ on a scale of 1-4+ (4+ denoting massive necrosis with greater than 90% of hepatocytes destroyed), and the mean SGOT value was 3,700 ± 690 U. In the dual hormone-treated group, liver cell necrosis was only about half as extensive as in controls, and SGOT averaged 1,820 ± 460 U. By 72-96 hr, the dual hormone-treated surviving animals showed gradual histological recovery, and in those surviving 144 hr, SGOT values and liver histology were almost normal. When ^3H-thymidine incorporation was used as an index of hepatic regeneration, infection with hepatitis caused a 10-fold reduction in DNA labeling during the first

24 hr. In the hormone-treated mice, DNA labeling rose progressively, peaking at 96 hr and returning to pre-infection levels by 144 hr. Whether the combination of these two pancreatic hormones is also beneficial in acute liver cell injury in man merits investigation.

2884 MORPHOLOGIC, BIOPHYSICAL, AND BIOCHEMICAL CONSEQUENCES OF LIGATION OF THE COMMON BILIARY DUCT IN THE DOG.

(Eng.) Carlson, E.; Zukoski, C. F.; Campbell, J.; Chvapil, M. (Arizona Medical Center, Tucson, AZ 85724). *Am. J. Pathol.* 86(2):301-320; 1977.

The common bile ducts of 32 adult mongrel dogs were ligated for 2 days to 6 weeks to simulate the pathologic conditions incurred by an obstructing stone or tumor and to study the effect of mechanical trauma on connective tissue reactivity. Sham-operated animals served as controls. Bile ducts were removed at sacrifice, and biophysical, morphologic, and biochemical parameters were measured. Bile duct ligation resulted in an immediate increase of intraductular pressure and was followed quickly by significant increases in the rate of collagen synthesis and the activity of prolyl hydroxylase. Subepithelial inflammation followed by marked increases in periductular fibrosis occurred. This fibroproliferative response was paralleled by peak levels of prolyl hydroxylase activity at 2 weeks postligation. Paradoxically, bile ducts were continuously distended throughout the ligation period, despite increased fibroplasia. Following 2 weeks of ligation, scanning electron microscopy revealed large crater-like fenestrae in ductular epithelial surfaces. This was followed by focal epithelial sloughing. The continuous distention and epithelial necrosis may be due to biliary stasis and/or subepithelial infiltration of bile through epithelial fenestrae. This hypothesis is supported by studies showing that collagen extractibility is markedly increased by the addition of bile to the homogenate.

2885 STRUCTURAL AND FUNCTIONAL CHANGES IN RAT PORTAL VEINS AFTER EXPERIMENTAL PORTAL HYPERTENSION.

(Eng.) Johansson, B. (Dept. Physiology and Biophysics, Univ. Lund, Lund, Sweden). *Acta Physiol. Scand.* 98(3): 381-383; 1976

The structural and functional response of portal veins to increased pressure in the absence of any general hypertensive disease was studied in anesthetized Sprague-Dawley rats. In rats with partial occlusion produced by tying silk ligatures around the portal vein, the portal pressures averaged 20.8 cm H_2O; in sham-operated and non-operated controls, the average portal pressure was 10.4 cm H_2O. Portal vein preparations from the hypertensive animals contracted at lower frequencies or were devoid of spontaneous activity; in controls the pattern of spontaneous activity was 2-4 phasic contractions/min. The preparations from hypertensive animals were less responsive to noradrenalin, corresponding to a mean change in ED_{50} from about 4.0×10^{-7} to 6.9×10^{-7} M. The optimal length for active force development in a length-tension study corresponded to a preload of about 5 mN in both control and hypertensive preparations. However, the maximal contractile force elicited by noradrenalin at the optimal lengths was 22.5 ± 2.9 mN in seven hypertensive veins, compared to 11.2 ± 1.0 mN in the controls. Also, the hypertensive vessels showed greater maximal contractions to noradrenalin than their sham-operated controls. The hypertensive vessel was markedly dilatated, and the wall thickness was increased in comparison with controls. This study reveals a rapid structural response of the portal vein to increased pressure load associated with changes in responsiveness and contractility of the smooth muscle.

2886 INDUCTION OF PINOCYTOSIS IN RAT HEPATOCYTES BY PARTIAL HEPATECTOMY.

(Eng.) Mori, M.; Novikoff, A. B. (Sapporo Medical Coll., Sapporo, 060, Japan). *J. Cell Biol.* 72(3):695-706; 1977.

The induction of pinocytosis in rat hepatocytes by 2/3-hepatectomy was investigated. Droplets of up to 20 µm in diameter developed initially by addition to smaller pinocytic structures, and later by fusion with lysosomes. The droplets contained a material with an electron microscopic periodicity characteristic of fibrin, and they were PAS-positive, as is plasma. Plasma glycoproteins are considered to be major components of the droplets. The droplets were membrane delimited, as seen after perfusion fixation. The droplets were positive for three lysosomal hydrolases identified cytochemically: acid phosphatase, *N*-acetyl-β-glucosaminidase, and β-glucuronidase. Light and electron microscopy showed that these activities were acquired by fusion with lysosomes, mostly autophagic vacuoles and residual bodies, both of which became numerous after partial hepatectomy. Pinocytic structures were frequently seen afte partial hepatectomy, although they were rare in norma liver. They were most easily observed if horseradis peroxidase (HRP) was injected i.v. before sacrifice and sections were incubated for HRP cytochemistry. The low dose of HRP employed (10 mg/100 g) did not induce pinocytosis in controls, either in untreated rats or rats subjected to laparotomy, including palpation of the liver. In partially hepatectomized rats, even a much smaller dose of i.v. HRP (3.3 mg/100 g) visualized the pinocytic structures in hepatocytes (coated vesicles, channels, cuplike bodies, and droplets). Kupffer cells pinocytosed much HRP in both control and partially hepatectomized rats.

2887 BILIARY FUNCTION AFTER LIVER TRANSPLANTATION.

(Eng.) Daloze, P.; Fourtanier, G.; Beaudouin, M.; Corman, J.; Smeesters, C.; Saric, J. (Hopital Notre-Dame, 1560 E. Sherbrooke St., Montrea H2L 4K8, Canada). *Transplant. Proc.* 9(1):309-312; 1977.

e effects of immunosuppression, liver isolation,
nervation, and immunologic attack on biliary
nction were studied in dogs following experimental
ver transplantation. Controls underwent laparo-
my only. Four other groups of dogs underwent the
llowing procedures: laparotomy plus immunosup-
ession (azathioprine, 3 mg/kg, reduced to 1 mg/kg
ter the first day; prednisolone, 1 mg/kg, reduced
0.5 mg/kg), autotransplantation, homotransplan-
tion, or homotransplantation plus immunosuppres-
on. Thirty of 49 dogs survived one of these pro-
dures for more than 3 days. Of these animals,
e mean survival among the animals in the respec-
ve groups was 12.1, 12.3, 14.2, 7.2, and 10.7
ys. In the first three groups, maximal survival
s arbitrarily limited to 15 days. In the last two
oups, no animal survived longer than 14 days. Im-
nosuppression alone did not affect bile salt secre-
on, bile flow, or bile salts. The surgical mani-
lations of either auto- or homotransplantation had
ly a slight effect on bile secretion. These alter-
ions disappeared after operation for the auto-
ansplanted recipients, which seems to rule out
ver denervation as the cause of early changes.
jection was accompanied by a severe deterioration
biliary secretion, but was less in immunosup-
essed recipients.

88 CORRECTION OF HYPERBILIRUBINEMIA IN THE GLUCURONYLTRANSFERASE-DEFICIENT RAT BY TRAPORTAL HEPATOCYTE TRANSPLANTATION.

(Eng.)
oth, C. G.; Arborgh, B.; Bjorken, C.; Sundberg,
; Lundgren, G. (Huddinge Hosp., Stockholm, Sweden).
ansplant. Proc. 9(1):313-316; 1977.

olated hepatocytes from normal Wistar rats were
ansplanted intraportally and i.m. in hyperbili-
binemic, uridine diphosphate-glucuronyltrans-
rase-deficient Gunn rats. The rats received
ther 25-35 x 10^6 hepatocytes intraportally or
x 10^6 cells i.m. Postoperatively, the re-
pients received cyclophosphamide (5 mg/kg/day).
o groups of Gunn rats received Wistar hepatocytes
traportally. In the first group, 13 of 18 sur-
ved; the other 5 died within 5 days with
vere liver damage and extensive necrosis. Ten
ys after transplantation, the average bilirubin
the surviving animals had decreased to 79% of
e preoperative value. In the second group, all
animals survived. After 10 days, the average
lirubin had decreased to 76%, and at 28 days, the
vel had dropped to 66% of the initial value. The
rum bilirubin decreased in all but one of the
imals. In hepatic specimens obtained from animals
crificed 10 days after transplantation, aggregates
well-preserved hepatocytes were found in the
stal portal branches and in the sinusoids in 9 of
livers. In most instances, the hepatic tissue
rrounding the intravascular cell plugs was morpho-
gically intact. Six of seven control Gunn rats
at had received intraportal injections of hepato-
tes from other Gunn rats survived, and the serum
lirubin remained unchanged at 10 and 28 days after
ansplantation. Five of six Gunn rats that had
ceived Wistar hepatocytes i.m. survived. Serum
lirubin was not reduced, despite morphological evidence of excellent engraftment. It appears that normal Wistar rat hepatocytes injected intraportally into uridine diphosphate-glucuronyltransferase-deficient Gunn rats serve as a source of the missing enzyme.

2889 ELEVEN AND TWO-THIRDS YEARS' SURVIVAL AFTER CANINE ORTHOTOPIC LIVER TRANSPLANTATION.

(Eng.) Starzl, T. E.; Porter, K. A.; Putnam, C. W. (Univ. Colorado Medical Center, Denver, CO 80262). *Transplantation* 23(2):168-171; 1977.

The autopsy findings of a mongrel dog that survived 11 yr and 8 months after orthotopic liver transplantation are presented. Immunosuppression with azathioprine had been discontinued 120 days after transplantation, and the dog remained well until 1 or 2 days before its death at age 14 yr. The immediate cause of death was congestive heart failure, but a potentially lethal biliary duct complication was present, which would have independently caused death within a short time. The reconstructed vena cava above and below the liver and the portal vein were normal. To arterialize the liver, a segment of donor aorta in continuity with the hepatic artery had been anastomosed to the infrarenal recipient aorta. Although the hepatic artery was grossly normal, the homograft aorta had extensive calcified atherosclerosis. Biliary reconstruction was with cholecystoduodenostomy after ligation of the distal common duct. The gallbladder, the common duct, and all the intrahepatic ducts were filled with stones or else with a soft, green or orange sludge. Stone analysis revealed predominantly bilirubin. Histopathological evaluation of the homograft revealed portal fibrosis and linking of the enlarged portal tracts to one another by connective tissue septa. There was concentric scarring around the interlobular and septal bile ducts and proliferation of ductules at the margins of the portal tracts. Many of the larger bile ducts were dilated and filled with inspissated bile. The changes were typical of chronic large duct biliary obstruction, emphasizing that the reconstructed biliary duct system is the weak point of liver transplantation. There was no evidence of liver rejection.

2890 SERUM AND BILE MODIFICATIONS IN THE GUINEA-PIG FOLLOWING CHRONIC TREATMENT WITH PGE_1 AND PGE_2.

(Eng.) Rodrigo, L. R.; Pozo, F.; Marin, B.; Schiaffini, O. (Dept. Physiology, Univ. Oviedo, Spain). *Experientia* 32(12):1604-1605; 1976.

The effects of chronic prostaglandin E_1 and E_2 (PGE_1 and PGE_2) treatment were studied in the serum and bile of guinea pigs. The animals received i.p. injections of prostaglandins (0.1 μg) on alternate days for 2 weeks. PGE_1 increased the mean serum cholesterol level (62.25 ± 3.49 mg/100 ml versus 46.15 ± 2.91 mg/100 ml in controls, $p<0.01$), but did not change the bile cholesterol or serum lipid levels. PGE_2 decreased the mean serum cholesterol level to 42.85 ± 2.67 mg/100 ml and increased the mean serum lipid level from 393.25 ± 20.36 to 623.00 ± 32.17 mg/100 ml ($p<0.01$). The biliary lipid level was decreased from 382.50 ± 27.32 mg/100 ml to 193.25 ± 18.23 mg/100 ml by PGE_1 treatment

($p<0.01$). The bile volume was decreased from a control level of 3.89 $\pm$ 0.13 ml to 2.89 $\pm$ 0.24 ml by PGE_1 and to 2.90 $\pm$ 0.10 ml by PGE_2 ($p<0.01$).
